November 27, 2023

Abstract
Recent results show that estimates defined by over-parametrized deep neural networks learned by applying gradient descent to a regularized empirical $L_2$ risk are universally consistent and achieve good rates of convergence. In this paper, we show that the regularization term is not necessary to obtain similar results. In the case of a suitably chosen initialization of the network, a suitable number of gradient descent steps, and a suitable step size we show that an estimate without a regularization term is universally consistent for bounded predictor variables. Additionally, we show that if the regression function is Hölder smooth with Hölder exponent $1/2 \leq p \leq 1$, the $L_2$ error converges to zero with a convergence rate of approximately $n^{-1/(1+d)}$. Furthermore, in case of an interaction model, where the regression function consists of a sum of Hölder smooth functions with $d^*$ components, a rate of convergence is derived which does not depend on the input dimension $d$.

AMS classification: Primary 62G08; secondary 62G20.

Key words and phrases: interaction models, neural networks, nonparametric regression, over-parametrization, rate of convergence, universal consistency.

1. Introduction

1.1. Deep learning
In the last decade, deep learning, i.e. the application of deep neural networks to data, has gained a lot of attraction in practical applications as well as in theoretical considerations and achieves impressive results. For instance, in natural science AlphaFold can predict protein structures (c.f. Billings et al. (2019)) or AlphaZero is able to outperform humans in three popular board games (c.f. McGrath et al. (2022)). Furthermore, the chatbot
ChatGPT is one of the most capable language models nowadays, consisting of 175 billion parameters (c.f. Zong and Krishnamachari (2022)). Another example is the text-to-image model DALL-E-2, which consists of 3.5 billion parameters (c.f. Hunt (2023)). These observations suggest that a large number of parameters is very useful in practical applications of deep learning.

From a theoretical point of view this great success cannot yet be fully explained. However, there exist already some results concerning deep neural networks. For example, results on the rate of convergence of least squares estimates based on deep neural networks have been derived (cf., e.g., Bauer and Kohler (2019), Schmidt-Hieber (2020), Kohler and Langer (2021)).

Nevertheless, the above results neglect two features which have turned out to be very important for practical applications. First, in contrast to the results above, in practice estimates are computed using gradient descent instead of least squares. The second property they ignore is that practical applications often use over-parametrized neural networks. A network is called over-parametrized if the number of its parameters is much larger than the sample size.

In this paper we consider a suitable over-parametrized deep neural network estimate computed by gradient descent and analyze its statistical performance in a nonparametric regression setting.

1.2. Nonparametric regression

We analyze deep neural network estimates in the context of nonparametric regression. To do this we consider a random $\mathbb{R}^d \times \mathbb{R}$-valued vector $(X, Y)$ with $\mathbb{E}Y^2 < \infty$. Here we are interested in the dependence of the so-called response variable $Y$ on the value of the observation vector $X$. We assume that it is possible to observe data of $(X, Y)$. This dataset is given by

$$D_n = \{(X_1, Y_1), \ldots, (X_n, Y_n)\}$$

where $(X, Y),(X_1, Y_1),\ldots,(X_n, Y_n)$ are independent and identically distributed (i.i.d.).

Our aim is to construct an estimate $m_n(x) := m_n(x, D_n)$ of the corresponding regression function $m : \mathbb{R}^d \rightarrow \mathbb{R}$ with $m(x) = \mathbb{E}\{Y|X = x\}$ such that the $L_2$ error

$$\int |m_n(x) - m(x)|^2 \mathbb{P}_X(dx)$$

is small (cf. e.g. Györfi et al. (2002) for a detailed introduction to nonparametric regression).

There exist different modes of convergence. An important property an estimate should satisfy is to be universally consistent. Universal consistency means that the $L_2$ error converges to zero for all distributions of $(X, Y)$. But it does not provide any information about a rate of convergence of the $L_2$ error. As shown in Theorem 7.2 and Problem 7.2 in Devroye, Györfi and Lugosi (1996) a rate of convergence cannot be derived in general since there always exists a distribution such that the $L_2$ error converges to zero arbitrarily slowly. Thus, in order to derive non-trivial results about the rate of convergence, we need
to restrict the class of regression functions. To do this we use the following definition of 
\((p, C)\) smoothness.

**Definition 1.** Let \( p = q + s \) for some \( q \in \mathbb{N}_0 \) and \( 0 < s \leq 1 \). A function \( m : \mathbb{R}^d \to \mathbb{R} \) is called \((p, C)\)-smooth, if for every \( \alpha = (\alpha_1, \ldots, \alpha_d) \in \mathbb{N}_0^d \) with \( \sum_{j=1}^d \alpha_j = q \) the partial derivative \( \frac{\partial^\alpha m}{\partial x_1^{\alpha_1} \ldots \partial x_d^{\alpha_d}} \) exists and satisfies

\[
\left| \frac{\partial^\alpha m}{\partial x_1^{\alpha_1} \ldots \partial x_d^{\alpha_d}}(x) - \frac{\partial^\alpha m}{\partial x_1^{\alpha_1} \ldots \partial x_d^{\alpha_d}}(z) \right| \leq C \cdot \| x - z \|^s
\]

for all \( x, z \in \mathbb{R}^d \), where \( \| \cdot \| \) denotes the Euclidean norm. For \( p \leq 1 \), the function \( m \) is called Hölder-smooth with exponent \( p \) and Hölder-constant \( C \).

Stone (1982) showed that the optimal minimax rate of convergence in nonparametric regression for \((p, C)\)-smooth functions is given by \( n^{-2p/(2p+d)} \).

### 1.3. Main results

The goal of this paper is to study over-parametrized deep neural networks trained by gradient descent from a statistical point of view.

In this context we define an estimate which fits an over-parametrized deep neural network via gradient descent to the data. The output of the network is defined as a linear combination of a large number of fully connected deep neural networks. The main feature of this work is that we do not need a regularization term in the empirical \( L_2 \) risk. To derive the results for the empirical \( L_2 \) risk without a regularization term, we use a new approach to analyze the optimization error. Previous methods used that the gradient of the empirical \( L_2 \) risk is Lipschitz continuous (Braun et al. (2024)) or they used the convexity of the empirical \( L_2 \) risk (Yehudai and Shamir (2022)) to analyze the optimization error. In our work, we combine these two techniques (cf. Lemma 1 below).

Firstly, we prove that for a bounded support of the input data the estimate is universally consistent. Secondly, we analyze the rate of convergence of the over-parametrized deep neural network estimate. In Theorem 2 below, we show that if the regression function is \((p, C)\)-smooth with \( p \in [1/2, 1] \), then the expected \( L_2 \) error of the truncated estimate tends to zero, with a rate of convergence close to

\[
n^{-\frac{1}{1+s}}.
\]

Furthermore, in case of an interaction model, i.e. if the regression function is a sum of \((p, C)\)-smooth functions where each function depends on at most \( d^* \) of the \( d \) components of \( X \), the estimate achieves a rate of convergence which is close to

\[
n^{-\frac{1}{1+d^*}}
\]

and does not depend on the input dimension \( d \).
1.4. Discussion of related results

From a theoretical point of view, there have been many interesting results in the past years. For instance, in the case of a suitably defined least squares estimate based on a multilayer neural network, Kohler and Krzyżak (2017) were able to derive a rate of convergence of $n^{-\frac{2p}{2p+d^*}}$ for $(p, C)$-smooth regression functions, which satisfy a model where the functions consist of a composition of functions applied to at most $d^*$ components of its inputs, with $p \leq 1$. This rate does not depend on the input dimension $d$. Bauer and Kohler (2019) were able to show the same assertion for $p > 1$, provided that the activation function is sufficiently smooth. Under the additional condition of the so-called sparsity of the networks, Schmidt-Hieber (2020) showed the same rate of convergence for neural network estimates with ReLU activation function in case that the regression function satisfies a kind of hierarchical composition model. The property of sparsity is not necessary to obtain this rate of convergence for a regression function satisfying a hierarchical composition model (Kohler and Langer (2021)). Suzuki (2018) and Suzuki and Nitanda (2021) were able to show that this dimensional reduction can be achieved even under weaker assumptions on the smoothness of the regression function. For this purpose they considered deep learning with ReLU activation function for functions in Besov spaces.

In classical machine learning theory, the goal was to avoid over-parametrized neural networks. It was thought that these networks lead to an overfitting of the weights to the data and therefore generalize poorly to new data. Therefore, it was desired to obtain a bias-variance trade-off. The model should be complex enough to represent the structure of the underlying data, but simple enough to avoid overfitting. However, in practical applications, over-parametrized neural networks are often used very successfully and achieve high accuracy on new test data. This phenomenon has been studied recently by many different researchers (c.f., e.g. Belkin et al. (2019), Frei, Chatterji and Bartlett (2022) and the literature cited therein).

Belkin et al. (2019) were able to reconcile classical theory with new findings in practical applications and identified a pattern of performance dependence on unseen model capacity data and the underlying mechanism of emergence. This dependence is represented by the so-called double descent curve. This curve shows that if the model capacity is greater than the interpolation threshold, the test risk will decrease again.

In recent years, much work has focused on the capacity of neural networks. They tried to understand the ability of neural networks to adapt to the training data either on a finite data set (Bubeck et al. (2020)) or with respect to neural networks trained by gradient methods (Daniely (2019), Daniely (2020)) or in neural tangent training (Montanari and Zhong (2020)). In addition Bartlett et al. (2020) and Belkin, Rakhlin and Tsybakov (2019) have already shown that over-parametrized neural networks can achieve good rates of convergence.

In practical applications the weights of neural network estimates are computed by gradient descent. So from a theoretical point of view it is very interesting to derive theoretical results for such estimates. Nitanda and Suzuki (2021) showed that the averaged stochastic gradient descent for over-parametrized neural networks with one hidden layer
can achieve the optimal minimax rate of convergence in a neural tangent kernel setting where the smoothness of the regression function is measured by the neural tangent kernel. Furthermore, it was shown that the (stochastic) gradient descent can find a global minimum of the empirical \( L_2 \) risk for suitable over-parametrized deep neural networks (Allen-Zhu, Li and Song (2019), Kawaguchi and Huang (2020), Arora et al. (2019), Du et al. (2018)).

However, Kohler and Krzyżak (2021) were able to exhibit that over-parametrized deep neural networks minimizing the empirical \( L_2 \) risk do not generalize well on new data, in the sense that the networks that minimize the empirical risk do not achieve the optimal minimax rate of convergence.

Braun et al. (2024) showed that under the assumption that the Fourier transform of the regression function decays fast enough, a suitably initialized estimate learned by gradient descent achieves (up to a logarithmic factor) a rate of convergence of \( n^{-\frac{1}{2}} \) which does not depend on the input dimension \( d \). This result is related to a classical result of Barron (1994). He was able to derive a similar rate of convergence for a least squares neural network estimate in case that the Fourier transform has a finite first moment, which requires that the function becomes smoother with increasing dimension. Kohler and Krzyżak (2022b) analyzed the same estimates in an over-parametrized setting and were able to derive an improved rate of convergence of \( n^{-\frac{2}{3}} \) for \( d = 1 \) using a suitably regularized \( L_2 \) risk.

The property of over-parametrization allows the gradient descent to find interpolating solutions that implicitly impose a regularization. This over-parametrization leads to benign overfitting (Bartlett, Montanari and Rakhlin (2021)).

Drews and Kohler (2022) showed the property of universal consistency for over-parametrized deep neural network estimates computed by minimizing the \( L_2 \) risk with gradient descent. For these estimates, that are computed minimizing a regularized \( L_2 \) risk via gradient descent, Kohler and Krzyżak (2022a) were able to derive a rate of convergence close to \( n^{-\frac{1}{2+d}} \) for suitably smooth regression functions. For this, they considered three key ingredients. Firstly, they used that with high probability a subset of the inner initial weights has good properties. For a suitable choice of the outer weights this causes a good approximation property. Secondly, for a suitably chosen number of gradient steps, a suitably chosen step size and suitably chosen bounds for the initial weights, they were able to use a metric entropy bound to control the generalizability of the estimate. Thirdly, they analyzed the optimization of the empirical \( L_2 \) risk by optimizing the outer weights during the gradient descent and by using a regularization term.

Kohler and Krzyżak (2022a) were also able to show a dimension-independent rate of convergence for interaction models close to \( n^{-\frac{1}{1+d}} \).

Our results are an extension of the results in Drews and Kohler (2022) and Kohler and Krzyżak (2022a). We show that the regularization term is not necessary. The estimate is universally consistent even by minimizing the empirical \( L_2 \) risk without a regularization term and achieves similar rates of convergence.
1.5. Notation

Throughout this paper we will use the following notation: The sets of natural numbers, real numbers and non-negative real numbers are denoted by \( \mathbb{N} \), \( \mathbb{R} \) and \( \mathbb{R}^+ \), respectively. For \( z \in \mathbb{R} \), we denote by \( \lfloor z \rfloor \) the smallest integer greater than or equal to \( z \) and by \( \lceil z \rceil \) the largest integer less than or equal to \( z \). The Euclidean norm of \( x \in \mathbb{R}^d \) is denoted by \( \| x \| \). For a function \( f : \mathbb{R}^d \to \mathbb{R} \), we refer to \( \| f \|_\infty = \sup_{x \in \mathbb{R}^d} |f(x)| \) as the supremum norm. Let \( F \) be a set of functions \( f : \mathbb{R}^d \to \mathbb{R} \), let \( x_1, \ldots, x_n \in \mathbb{R}^d \), set \( x^n_1 = (x_1, \ldots, x_n) \) and let \( p \geq 1 \). A finite collection \( f_1, \ldots, f_N : \mathbb{R}^d \to \mathbb{R} \) is called an \( L_p \) \( \varepsilon \)-cover of \( F \) on \( x^n_1 \) if for any \( f \in F \) there exists \( i \in \{1, \ldots, N\} \) such that

\[
\left( \frac{1}{n} \sum_{k=1}^n |f(x_k) - f_i(x_k)|^p \right)^{1/p} < \varepsilon.
\]

The \( L_p \) \( \varepsilon \)-covering number of \( F \) on \( x^n_1 \) is the size \( N \) of the smallest \( L_p \) \( \varepsilon \)-cover of \( F \) on \( x^n_1 \). It is denoted by \( \mathcal{N}_p(\varepsilon, F, x^n_1) \).

If \( A \) is a subset of \( \mathbb{R}^d \) and \( x \in \mathbb{R}^d \), then we set \( 1_A(x) = 1 \) if \( x \in A \) and \( 1_A(x) = 0 \) otherwise.

For \( z \in \mathbb{R} \) and \( \beta > 0 \) we define \( T_\beta z = \max\{-\beta, \min\{\beta, z\}\} \). If \( f : \mathbb{R}^d \to \mathbb{R} \) is a function and \( F \) is a set of such functions, then we set \( (T_\beta f)(x) = T_\beta (f(x)) \) and

\[
T_\beta F = \{T_\beta f : f \in F\}.
\]

1.6. Outline

In Section 2 we define the estimate. The main results concerning the universal consistency and the rate of convergence of the deep neural network estimate learned by gradient descent are presented in Section 3. The proofs of the main results are given in Section 4.

2. Definition of the estimate

In order to define the estimate, let \( \sigma(x) = 1/(1 + e^{-x}) \) be the logistic squasher. For the neural network topology, we choose a linear combination of \( K_n \) fully connected neural networks with \( L \) layers and \( r \) neurons per layer. The output of the network is defined by

\[
f_w(x) = \sum_{j=1}^{K_n} w^{(L)}_{1,1,j} \cdot f^{(L)}_{j,1}(x)
\]

for some \( w^{(L)}_{1,1,1}, \ldots, w^{(L)}_{1,1,K_n} \in \mathbb{R} \), where \( f^{(L)}_{j,1} \) is recursively defined by

\[
f^{(l)}_{k,1}(x) = \sigma \left( \sum_{j=1}^r w^{(l-1)}_{k,i,j} \cdot f^{(l-1)}_{k,j}(x) + w^{(l-1)}_{k,i,0} \right)
\]
for some $w_{k,i,0}^{(l-1)}, \ldots, w_{k,i,r}^{(l-1)} \in \mathbb{R}$ ($l = 2, \ldots, L$) and
\[
f_{k,i}^{(1)}(x) = \sigma \left( \sum_{j=1}^{d} w_{k,i,j}^{(0)} \cdot x^{(j)} + w_{k,i,0}^{(0)} \right)
\]
for some $w_{k,i,0}^{(0)}, \ldots, w_{k,i,d}^{(0)} \in \mathbb{R}$.

We denote by $f^{(l)}_{k,i}$ the output of neuron $i$ in the $l$-th layer of the $k$-th fully connected network. By $w_{k,i,j}^{(l-1)}$ we denote the weight between neuron $j$ in the $(l-1)$-th layer and neuron $i$ in the $l$-th layer of the $k$-th fully connected network.

The number of weights of the neural network is given by
\[
W_n = K_n \cdot (1 + (r + 1) + (L - 2) \cdot r \cdot (r + 1) + r \cdot (d + 1)).
\]

To obtain the estimate, we want to learn the weights using gradient descent. For this we initialize the weights $w^{(0)} = ((w^{(0)})_{k,i,j}^{(l)})_{k,i,j,l}$ by setting
\[
(w^{(0)})_{1,1,k}^{(L)} = 0 \quad \text{for } k = 1, \ldots, K_n,
\]
and by choosing all components of $w^{(0)}$ such that they are independent. We choose the weights $(w^{(0)})_{k,i,j}^{(l)}$ with $l \in \{1, \ldots, L - 1\}$ uniformly distributed on $[-20d \cdot (\log n)^2, 20d \cdot (\log n)^2]$ and $(w^{(0)})_{k,i,j}^{(0)}$ uniformly distributed on $[-8d \cdot (\log n)^2 \cdot n^\tau, 8d \cdot (\log n)^2 \cdot n^\tau]$ for some fixed $\tau > 0$.

Set
\[
\lambda_n = \frac{1}{t_n}
\]
and compute
\[
w^{(t+1)} = w^{(t)} - \lambda_n \cdot (\nabla_w F_n)(w^{(t)})
\]
for $t = 0, \ldots, t_n - 1$ where
\[
F_n(w) = \frac{1}{n} \sum_{i=1}^{n} |f_w(X_i) - Y_i|^2
\]
is the empirical $L_2$ risk of the network $f_w$ on the training data. The number of gradient descent steps $t_n$ will be chosen in Section 3 below.

The estimate is then defined by
\[
m_n(x) = T_{\beta_n} f_{w(t_n)}(x),
\]
where $\beta_n = c_1 \cdot \log n$.

Because of (4) we have
\[
F_n(w^{(0)}) = \frac{1}{n} \sum_{i=1}^{n} |Y_i|^2.
\]
3. Main results

3.1. Universal consistency

Our first result is the following theorem which presents the universal consistency for bounded $X$ of an estimate learned by gradient descent using the empirical $L_2$ risk without a regularization term.

**Theorem 1.** Let $\sigma(x) = 1/(1 + e^{-x})$ be the logistic squasher, and let $K_n, L, r \in \mathbb{N}$ and $\tau \in \mathbb{R}_+$. Furthermore, assume that $L \geq 2$, $r \geq 2d$, $\tau = 1/(d+1)$,

$$\frac{K_n}{n^\kappa} \to 0 \quad (n \to \infty)$$

(5)

for some $\kappa > 0$,

$$\frac{K_n}{n^{r+2}} \to \infty \quad (n \to \infty),$$

(6)

and $\beta_n = c_1 \cdot \log n$ for some $c_1 > 0$. Let the estimate $m_n$ be defined as in Section 2 with

$$t_n = \lceil c_2 \cdot L_n \rceil$$

(7)

for some $c_2 \geq 1$ and $L_n > 0$ which satisfies

$$L_n \geq K_n^{3/2} \cdot (\log n)^{6L+5}.$$  

Then we have

$$\mathbb{E} \int |m_n(x) - m(x)|^2 P_X(dx) \to 0 \quad (n \to \infty)$$

for every distribution of $(X,Y)$ where $\text{supp}(X)$ is bounded and $\mathbb{E}Y^2 < \infty$.

**Remark 1.** The estimate is over-parametrized in the sense that the number of its parameters is much larger than the sample size. This is due to condition (6), which requires that $K_n$ is asymptotically larger than $n^{r+2} \geq n^{2d+2}$. Theorem 1 shows that using the empirical $L_2$ risk without a regularization term, a suitable large number of steps, and a step size which is equal to the reciprocal of the number of steps provides a good generalization of new independent data.

**Remark 2.** The proof uses that the inner weights are chosen with high probability such that for properly chosen outer weights of the neural networks, the corresponding neural network has a small empirical $L_2$ risk. Hence, this neural network is based on representation guessing instead of representation learning.

3.2. Rate of convergence for $(p,C)$-smooth regression functions

Besides the result about the universal consistency of the estimate, it is interesting how fast the expected $L_2$ error converges to 0. Therefore, in the next theorem a rate of convergence for $(p,C)$-smooth functions is derived.
Theorem 2. Let $n \in \mathbb{N}$ and let $(X, Y), (X_1, Y_1), \ldots, (X_n, Y_n)$ be independent and identically distributed $\mathbb{R}^d \times \mathbb{R}$ valued random variables which satisfy $\text{supp}(X) \subseteq [0, 1]^d$ and

$$\mathbb{E} \left\{ e^{c_3 Y^2} \right\} < \infty$$

for some $c_3 > 0$. Assume that the corresponding regression function $m(x) = \mathbb{E}\{Y|X = x\}$ is $(p, C)$-smooth for some $1/2 \leq p \leq 1$ and some $C > 0$.

Let $\sigma(x) = 1/(1 + e^{-x})$ be the logistic squasher, let $L, r \in \mathbb{N}$ with $L \geq 2$ and $r \geq 2d$. Set $\beta_n = c_1 \cdot \log n$ for some $c_1 > 0$,

$$K_n = n^{6d + r + 2},$$

$$\tau = \frac{1}{1 + d}.$$

Define the estimate $m_n$ as in Section 2 with

$$t_n = [c_4 \cdot L_n]$$

for some $c_4 \geq 1$ and $L_n > 0$ which satisfies

$$L_n \geq K_n^{3/2} \cdot (\log n)^{6L + 2}$$

and assume that

$$c_1 \cdot c_3 \geq 2.$$ (10)

Then we have for any $\epsilon > 0$

$$\mathbb{E} \int |m_n(x) - m(x)|^2 \mathbb{P}_X(dx) \leq c_5 \cdot n^{-\frac{1}{1+d} + \epsilon}.$$

Remark 3. According to Stone (1982) the optimal minimax rate of convergence for $(p, C)$-smooth functions is $n^{-\frac{2p}{2p+d}}$. Thus, the rate of convergence derived from Theorem 2 is almost optimal for $p = \frac{1}{2}$. Unfortunately, if $p > \frac{1}{2}$, the rate of convergence derived above is not almost optimal. We assume that this is not a property of the estimate, but rather a consequence of our proof.

3.3. Rate of convergence in an interaction model

The aim of this subsection is to modify the estimate defined above in order to obtain a rate of convergence that does not depend on $d$. For this we assume that the regression function satisfies

$$m(x) = \sum_{I \subseteq \{1, \ldots, d\} : |I| = d^*} m_I(x_I),$$

with $1 \leq d^* < d$. The functions $m_I : \mathbb{R}^{d^*} \to \mathbb{R}$ ($I \subseteq \{1, \ldots, d\}$, $|I| = d^*$) are $(p, C)$-smooth functions and we use the notation

$$x_I = (x^{(j_1)}, \ldots, x^{(j_{d^*})})$$
for $I = \{j_1, \ldots, j_d^*\}$.

The neural network is then given by

$$ f_w(x) = \sum_{I \subseteq \{1, \ldots, d\} : |I| = d^*} f_{w_I}(x_I) $$

where $f_{w_I}$ is defined by (1)–(3) with $d$ replaced by $d^*$ and weight vector $w_I$, where

$$ w = (w_I)_{I \subseteq \{1, \ldots, d\}, |I| = d^*}. $$

We initialize the weights $w^{(0)} = (\{(w_I^{(0)})_{k,i,j}^{(l)}\}_{k,i,j,l})_{I \subseteq \{1, \ldots, d\}, |I| = d^*}$ by setting

$$ (w_I^{(0)})^{(L)}_{1,1,k} = 0 \quad (k = 1, \ldots, K_n, I \subseteq \{1, \ldots, d\}, |I| = d^*) $$

and by choosing all weights $(w_I^{(0)})_{k,i,j}$ such that they are independent. We choose the weights $(w_I^{(0)})_{k,i,j}$ with $l \in \{1, \ldots, L - 1\}$ uniformly distributed on the interval $[-20d^* \cdot (\log n)^2, 20d^* \cdot (\log n)^2]$ and we choose $(w_I^{(0)})_{k,i,j}$ uniformly distributed on the interval $[-8d \cdot (\log n)^2 \cdot n^\tau, 8d \cdot (\log n)^2 \cdot n^\tau]$ where $\tau = \frac{1}{1 + d^*}$ ($I \subseteq \{1, \ldots, d\}$ with $|I| = d^*$).

Similar as above we define the estimate as follows: Set

$$ \lambda_n = \frac{1}{t_n} $$

and compute

$$ w^{(t+1)} = w^{(t)} - \lambda_n \cdot (\nabla_w F_n)(w^{(t)}) $$

for $t = 0, \ldots, t_n - 1$ where

$$ F_n(w) = \frac{1}{n} \sum_{i=1}^{n} |f_w(x_i) - Y_i|^2 $$

is the empirical $L_2$ risk of the network $f_w$ on the training data. The number of gradient descent steps $t_n$ will be chosen in Theorem 3 below.

The estimate is then defined by

$$ m_n(x) = T_{\beta_n} f_{w^{(t_n)}}(x) $$

where $\beta_n = c_1 \cdot \log n$.

**Theorem 3.** Let $d \in \mathbb{N}, d^* \in \{1, \ldots, d\}$, $1/2 \leq p \leq 1$. Furthermore, let $C > 0$, $n \in \mathbb{N}$ and let $(X, Y), (X_1, Y_1), \ldots, (X_n, Y_n)$ be independent and identically distributed $\mathbb{R}^d \times \mathbb{R}$ valued random variables such that $\text{supp}(X) \subseteq [0, 1]^d$ and

$$ \mathbb{E}\{e^{C_2 Y^2}\} < \infty $$
holds for some \( c_3 > 0 \). Assume that the corresponding regression function \( m(x) = \mathbb{E}\{Y | X = x\} \) satisfies
\[
m(x) = \sum_{I \subseteq \{1, \ldots, d\}, |I| = d^*} m_I(x_I) \quad (x \in [0,1]^d)
\]
for some \((p,C)\)-smooth functions \( m_I : \mathbb{R}^{d^*} \to \mathbb{R} \) \((I \subseteq \{1, \ldots, d\}, |I| = d^*)\).

Let \( \sigma(x) = 1/(1 + e^{-x}) \) be the logistic squasher. Let \( L, r \in \mathbb{N} \) with \( L \geq 2 \) and \( r \geq 2d^* \). Set \( \beta_n = c_1 \cdot \log n \),
\[
K_n = n^{6d^*+r+2} \quad \text{and} \quad \tau = \frac{1}{1 + d^*}.
\]

Define the estimate \( m_n \) as in Section 3.3 with
\[
t_n = \lceil c_6 \cdot L_n \rceil
\]
for some \( c_6 \geq 1 \) and \( L_n > 0 \) which satisfies
\[
L_n \geq K_n^{3/2} \cdot (\log n)^{6L+2}
\]
and assume that
\[
c_1 \cdot c_3 \geq 2. \quad (11)
\]

Then we have for any \( \epsilon > 0 \)
\[
\mathbb{E} \int |m_n(x) - m(x)|^2 \mathbb{P}_X(dx) \leq c_7 \cdot n^{-\frac{1}{4d^*+r} + \epsilon}.
\]

**Remark 4.** The optimal minimax rate of convergence \( n^{-\frac{2p}{2p+d}} \) derived by Stone (1982) suffers from the curse of dimensionality. This means that if \( d \) is very large compared to \( p \), the rate of convergence becomes extremely slow. However, Stone (1994) has already established that under appropriate assumptions it is possible to circumvent the curse of dimensionality. In Theorem 3, we were able to show that under the above assumptions on the regression function, the over-parametrized neural network estimate can also circumvent the curse of dimensionality.

4. Proofs

4.1. Auxiliary results for the proof of Theorem 1

In this section we will present auxiliary results that are necessary for the proof of Theorem 1. The first auxiliary result enables us to analyze the gradient descent.
Lemma 1. Let \( d_1, d_2 \in \mathbb{N} \), let \( (u_0, v_0) \in \mathbb{R}^{d_1} \times \mathbb{R}^{d_2} \), let \( F : \mathbb{R}^{d_1} \times \mathbb{R}^{d_2} \to \mathbb{R}_+ \) be a continuously differentiable function and set
\[
A = \left\{ (u, v) \in \mathbb{R}^{d_1} \times \mathbb{R}^{d_2} : \| (u, v) - (u_0, v_0) \| \leq 2 \cdot \sqrt{F(u_0, v_0)} + 1 \right\}.
\]

Let \( u^* \in \mathbb{R}^{d_1} \) and assume that for some \( D_n, L_n > 0 \) it holds
\[
F(u^*, v) \text{ is convex for all } v \in \mathbb{R}^{d_2},
\]
for all \((u, v) \in A,
\[
\| (\nabla_{(u,v)} F)(u, v) \| \leq L_n \tag{12}
\]
for all \((u_1, v_1), (u_2, v_2) \in A \) and
\[
|F(u^*, v) - F(u_1, v_1)| \leq D_n \cdot \| u^* - v \| \| v - v_0 \| \tag{14}
\]
for all \( v \in \{ \tilde{v} : \| \tilde{v} - v_0 \| \leq \sqrt{2 \cdot F(u_0, v_0)} \} \).

Set
\[
\begin{align*}
&u_{t+1} = u_t - \lambda \cdot (\nabla_u F)(u_t, v_t), \\
v_{t+1} = v_t - \lambda \cdot (\nabla_v F)(u_t, v_t)
\end{align*}
\]
for \( t = 0, 1, \ldots, t_n - 1 \), where
\[
t_n \geq L_n \quad \text{and} \quad \lambda = \frac{1}{t_n}.
\]

Then we have
\[
F(u_{t_n}, v_{t_n}) \leq F(u^*, v_0) + D_n \cdot \| u^* \| \cdot \sqrt{2 \cdot F(u_0, v_0)} + \frac{\| u^* - u_0 \|^2}{2} + \frac{F(u_0, v_0)}{t_n}.
\]

Furthermore, even if \( (14) \) does not hold, we have
\[
\| u_t - u_0 \| \leq \sqrt{2 \cdot F(u_0, v_0)} \quad \text{and} \quad \| v_t - v_0 \| \leq \sqrt{2 \cdot F(u_0, v_0)}
\]
for all \( t = 0, 1, \ldots, t_n \).

Proof. In the first step of the proof we show
\[
\frac{1}{t_n} \sum_{t=0}^{t_n-1} F(u_t, v_t) \leq \frac{1}{t_n} \sum_{t=0}^{t_n-1} F(u^*, v_t) + \frac{\| u^* - u_0 \|^2}{2} + \frac{1}{2 \cdot t_n} \sum_{t=0}^{t_n-1} \lambda \cdot \| (\nabla_u F)(u_t, v_t) \|^2. \tag{15}
\]
By convexity of \( u \mapsto F(u, v) \) we have
\[
\begin{align*}
F(u_t, v_t) - F(u^*, v_t) \\
&\leq \langle (\nabla_u F)(u_t, v_t), u_t - u^* \rangle
\end{align*}
\]
12
This implies

\[
\frac{1}{t_n} \sum_{t=0}^{t_n-1} F(u_t, v_t) - \frac{1}{t_n} \sum_{t=0}^{t_n-1} F(u^*, v_t) = \frac{1}{t_n} \sum_{t=0}^{t_n-1} (F(u_t, v_t) - F(u^*, v_t))
\]

\[
\leq \frac{1}{t_n} \sum_{t=0}^{t_n-1} \frac{1}{2} \cdot \lambda \cdot (\|u_t - u^*\|^2 - \|u_{t+1} - u^*\|^2) + \frac{1}{t_n} \sum_{t=0}^{t_n-1} \frac{\lambda}{2} \cdot \|\nabla_u F(u_t, v_t)\|^2
\]

\[
= \frac{1}{2} \cdot \sum_{t=0}^{t_n-1} (\|u_t - u^*\|^2 - \|u_{t+1} - u^*\|^2) + \frac{1}{2} \cdot \sum_{t=0}^{t_n-1} \lambda \cdot \|\nabla_u F(u_t, v_t)\|^2
\]

\[
\leq \frac{\|u_0 - u^*\|^2}{2} + \frac{1}{2} \cdot \sum_{t=0}^{t_n-1} \lambda \cdot \|\nabla_u F(u_t, v_t)\|^2.
\]

In the second step of the proof we show that

\[
\|\nabla_{(u,v)} F((u_t, v_t) + \tau \cdot ((u_{t+1}, v_{t+1}) - (u_t, v_t))) - (\nabla_{(u,v)} F(u_t, v_t))\|
\]

\[
\leq L_n \cdot \tau \cdot \|(u_{t+1}, v_{t+1}) - (u_t, v_t)\| \quad (16)
\]

for all \(\tau \in [0, 1]\) implies

\[
F(u_{t+1}, v_{t+1}) - F(u_t, v_t) \leq -\frac{1}{2} \cdot \lambda \cdot \|\nabla_u F(u_t, v_t)\|^2 - \frac{1}{2} \cdot \lambda \cdot \|\nabla_v F(u_t, v_t)\|^2. \quad (17)
\]

The function

\[
H : [0, 1] \to \mathbb{R}, \quad H(\tau) = F((u_t, v_t) + \tau \cdot ((u_{t+1}, v_{t+1}) - (u_t, v_t)))
\]

is continuously differentiable. By the fundamental theorem of calculus, assumption (16) and \(\lambda \leq 1/L_n\) we get

\[
F(u_{t+1}, v_{t+1}) - F(u_t, v_t) = H(1) - H(0) = \int_0^1 H'(\tau) d\tau
\]

\[
= \int_0^1 (\nabla_{(u,v)} F((u_t, v_t) + \tau \cdot ((u_{t+1}, v_{t+1}) - (u_t, v_t))) \cdot ((u_{t+1}, v_{t+1}) - (u_t, v_t))) d\tau
\]

\[
= \int_0^1 ((\nabla_{(u,v)} F)((u_t, v_t) + \tau \cdot ((u_{t+1}, v_{t+1}) - (u_t, v_t))) - (\nabla_{(u,v)} F)(u_t, v_t))
\]

13
\begin{align*}
&\cdot ((u_{t+1}, v_{t+1}) - (u_t, v_t))d\tau \\
&+ \int_0^1 (\nabla_{(u,v)} F)(u_t, v_t) \cdot ((u_{t+1}, v_{t+1}) - (u_t, v_t))d\tau \\
&\leq \int_0^1 \| (\nabla_{(u,v)} F)((u_t, v_t) + \tau \cdot ((u_{t+1}, v_{t+1}) - (u_t, v_t))) - (\nabla_{(u,v)} F)(u_t, v_t) \| \\
&\quad \cdot \| (u_{t+1}, v_{t+1}) - (u_t, v_t) \| d\tau \\
&+ (\nabla_{(u,v)} F)(u_t, v_t) \cdot ((u_{t+1}, v_{t+1}) - (u_t, v_t)) \\
&\leq \int_0^1 L_n \cdot \tau \cdot \| (u_{t+1}, v_{t+1}) - (u_t, v_t) \|^2 d\tau \\
&\quad + (\nabla_{(u,v)} F)(u_t, v_t) \cdot ((u_{t+1}, v_{t+1}) - (u_t, v_t)) \\
&= \frac{1}{2} \cdot L_n \cdot \| (u_{t+1}, v_{t+1}) - (u_t, v_t) \|^2 + (\nabla_{(u,v)} F)(u_t, v_t) \cdot ((u_{t+1}, v_{t+1}) - (u_t, v_t)) \\
&= \frac{1}{2} \cdot L_n \cdot (\lambda^2 \cdot \| (\nabla_u F)(u_t, v_t) \|^2 + \lambda^2 \cdot \| (\nabla_v F)(u_t, v_t) \|^2) \\
&\quad - \lambda \cdot \| (\nabla_v F)(u_t, v_t) \|^2 \\
&= \lambda \cdot \left( \frac{1}{2} \cdot L_n \cdot \lambda - 1 \right) \cdot \| (\nabla_u F)(u_t, v_t) \|^2 + \lambda \cdot \left( \frac{1}{2} \cdot L_n \cdot \lambda - 1 \right) \cdot \| (\nabla_v F)(u_t, v_t) \|^2 \\
&\leq -\frac{1}{2} \cdot \lambda \cdot \| (\nabla_u F)(u_t, v_t) \|^2 - \frac{1}{2} \cdot \lambda \cdot \| (\nabla_v F)(u_t, v_t) \|^2.
\end{align*}

In the third step of the proof we show

$$F(u_1, v_1) - F(u_0, v_0) \leq -\frac{1}{2} \cdot \lambda \cdot \| (\nabla_u F)(u_0, v_0) \|^2 - \frac{1}{2} \cdot \lambda \cdot \| (\nabla_v F)(u_0, v_0) \|^2.$$ 

By (12) we know

$$\| (\nabla_{(u,v)} F)(u_0, v_0) \| \leq L_n,$$

which implies for any $\tau \in [0, 1]$

$$\| (u_0, v_0) + \tau \cdot ((u_1, v_1) - (u_0, v_0)) - (u_0, v_0) \| \leq \lambda \cdot L_n.$$

Consequently we can conclude from (13) that (16) holds for $t = 0$, from which we get the assertion of step 3 by applying the result from step 2.

In the fourth step of the proof we show that by induction on $t$, that

$$F(u_{t+1}, v_{t+1}) - F(u_t, v_t) \leq -\frac{1}{2} \cdot \lambda \cdot \| (\nabla_u F)(u_t, v_t) \|^2 - \frac{1}{2} \cdot \lambda \cdot \| (\nabla_v F)(u_t, v_t) \|^2$$

holds for all $t \in \{0, 1, \ldots, t_n - 1\}$, and that

$$\| u_t - u_0 \| \leq \sqrt{2 \cdot F(u_0, v_0)} \quad \text{and} \quad \| v_t - v_0 \| \leq \sqrt{2 \cdot F(u_0, v_0)}$$

hold for all $t \in \{0, 1, \ldots, t_n\}$.

For $t = 0$ the assertion follows from step 3. So assume now that the assertion holds for some $t \in \{0, 1, \ldots, t_n - 1\}$. Then (12) implies

$$\| (\nabla_{(u,v)} F)(u_t, v_t) \| \leq L_n,$$
which implies for any $\tau \in [0, 1]$

$$
\|(u_t, v_t) + \tau \cdot ((u_{t+1}, v_{t+1}) - (u_t, v_t)) - (u_0, v_0)\| \leq \|(u_t, v_t) - (u_0, v_0)\| + \lambda \cdot L_n
$$

$$
\leq \sqrt{\|u_t - u_0\|^2 + \|v_t - v_0\|^2} + \lambda \cdot L_n \leq 2 \cdot \sqrt{F(u_0, v_0)} + \lambda \cdot L_n.
$$

Consequently we can conclude from (13) that (16) holds, from which we get by step 2

$$
F(u_{t+1}, v_{t+1}) - F(u_t, v_t) \leq -\frac{1}{2} \cdot \lambda \cdot \|(\nabla u F)(u_t, v_t)\|^2 - \frac{1}{2} \cdot \lambda \cdot \|(\nabla u F)(u_t, v_t)\|^2.
$$

Furthermore, we have

$$
\|u_{t+1} - u_0\|
\leq \sum_{s=0}^{t} \|u_{s+1} - u_s\|
\leq \sqrt{(t + 1) \cdot \sum_{s=0}^{t} \|u_{s+1} - u_s\|^2}
\leq \sqrt{(t + 1) \cdot \sum_{s=0}^{t} \lambda^2 \cdot \|(\nabla u F)(u_s, v_s)\|^2}
\leq \sqrt{2 \cdot (t + 1) \cdot \lambda \cdot \sum_{s=0}^{t} (F(u_s, v_s) - F(u_{s+1}, v_{s+1}))}
\leq \sqrt{2 \cdot (t + 1) \cdot \frac{1}{t_n} \cdot F(u_0, v_0)}
\leq \sqrt{2 \cdot F(u_0, v_0)}
$$

and

$$
\|v_{t+1} - v_0\|
\leq \sum_{s=0}^{t} \|v_{s+1} - v_s\|
\leq \sqrt{(t + 1) \cdot \sum_{s=0}^{t} \|v_{s+1} - v_s\|^2}
\leq \sqrt{(t + 1) \cdot \sum_{s=0}^{t} \lambda^2 \cdot \|(\nabla v F)(u_s, v_s)\|^2}
\leq \sqrt{2 \cdot (t + 1) \cdot \lambda \cdot \sum_{s=0}^{t} (F(u_s, v_s) - F(u_{s+1}, v_{s+1}))}
$$
\[
\leq \sqrt{2 \cdot (t + 1) \cdot \frac{1}{t_n} \cdot F(u_0, v_0)}
\]

\[
\leq \sqrt{2 \cdot F(u_0, v_0)}.
\]

In the fifth step of the proof we show the assertion. By the fourth step we know that \(F\) is monotonically decreasing hence it holds

\[
F(u_t, v_t) \leq \frac{1}{t_n} \sum_{t=0}^{t_n-1} F(u_t, v_t).
\]

Then we can conclude from the first step of the proof

\[
F(u_t, v_t) \leq \frac{1}{t_n} \sum_{t=0}^{t_n-1} F(u^*, v_t) + \frac{\|u^* - u_0\|^2}{2} + \frac{1}{2 \cdot t_n} \sum_{t=0}^{t_n-1} \lambda \cdot \|\nabla_u F(u_t, v_t)\|^2
\]

\[
\leq F(u^*, v_0) + \frac{1}{t_n} \sum_{t=0}^{t_n-1} \left| F(u^*, v_t) - F(u^*, v_0) \right|
\]

\[
+ \frac{\|u^* - u_0\|^2}{2} + \frac{1}{2 \cdot t_n} \sum_{t=0}^{t_n-1} \lambda \cdot \|\nabla_u F(u_t, v_t)\|^2.
\]

By (14) and the fourth step of the proof we get

\[
\frac{1}{t_n} \sum_{t=0}^{t_n-1} \left| F(u^*, v_t) - F(u^*, v_0) \right| \leq \frac{1}{t_n} \sum_{t=0}^{t_n-1} D_n \cdot \|u^*\| \cdot \|v_t - v_0\| \leq D_n \cdot \|u^*\| \cdot \sqrt{2 \cdot F(u_0, v_0)}.
\]

And as in the fourth step of the proof we get

\[
\sum_{t=0}^{t_n-1} \lambda \cdot \|\nabla_u F(u_t, v_t)\|^2 \leq 2 \cdot \sum_{t=0}^{t_n-1} \left( F(u_t, v_t) - F(u_{t+1}, v_{t+1}) \right) \leq 2 \cdot F(u_0, v_0).
\]

Summarizing the above results, the proof is complete.

With the following two results we can show that the assumptions (12) and (13) in the proof of Theorem 1 are satisfied.

**Lemma 2.** Let \(\sigma : \mathbb{R} \rightarrow \mathbb{R}\) be bounded and differentiable, and assume that its derivative is bounded. Let \(\alpha_n \geq 1, t_n \geq L_n, \gamma_n^* \geq 1, B_n \geq 1, r \geq 2d,\)

\[
|w^{(L)}_{1,k}| \leq \gamma_n^* \quad \text{for} \quad k = 1, \ldots, K_n,
\]

\[
|w^{(l)}_{k,i,j}| \leq B_n \quad \text{for} \quad l = 1, \ldots, L - 1
\]

and

\[
|w - v|_\infty^2 \leq \frac{8t_n}{L_n} \cdot \max\{F_n(v), 1\}.
\]

16
Then we have for $X_1, \ldots, X_n \in [-\alpha_n, \alpha_n]^d$

$$\| (\nabla F_n)(w) \| \leq c_8 \cdot K_n^{3/2} \cdot B_n^{2L} \cdot (\gamma_n^*)^2 \cdot \alpha_n^2 \cdot \sqrt{\frac{t_n}{L_n} \cdot \max \{ F_n(v), 1 \}}.$$  

**Proof.** The proof follows from Lemma 2 in Drews and Kohler (2022). For sake of completeness the proof is given in the appendix.  

**Lemma 3.** Let $\sigma : \mathbb{R} \to \mathbb{R}$ be bounded and differentiable, and assume that its derivative is Lipschitz continuous and bounded. Let $\alpha_n \geq 1$, $t_n \geq L_n$, $\gamma_n^* \geq 1$, $B_n \geq 1$, $r \geq 2d$ and assume

$$|\max\{(w_1)^{(L)}_{1,1,k}, (w_2)^{(L)}_{1,1,k}\}| \leq \gamma_n^* \quad \text{for } k = 1, \ldots, K_n,$$  

$$|\max\{(w_1)^{(l)}_{k,i,j}, (w_2)^{(l)}_{k,i,j}\}| \leq B_n \quad \text{for } l = 1, \ldots, L - 1$$  

and

$$\|w_2 - v\|^2 \leq 8 \cdot \frac{t_n}{L_n} \cdot \max \{ F_n(v), 1 \}.$$  

Then we have for $X_1, \ldots, X_n \in [-\alpha_n, \alpha_n]^d$

$$\| (\nabla F_n)(w_1) - (\nabla F_n)(w_2) \| \leq c_9 \cdot \max \{ \sqrt{F_n(v)}, 1 \} \cdot (\gamma_n^*)^2 \cdot B_n^{3L} \cdot \alpha_n^3 \cdot K_n^{3/2} \cdot \sqrt{\frac{t_n}{L_n} \cdot \|w_1 - w_2\|}.$$  

**Proof.** The proof follows from Lemma 3 in Drews and Kohler (2022). For sake of completeness the complete proof is given in the appendix.  

The next auxiliary result uses a metric entropy bound to control the complexity of a set of over-parametrized deep neural networks.

**Lemma 4.** Let $\alpha \geq 1$, $\beta > 0$ and let $A, B, C \geq 1$. Let $\sigma : \mathbb{R} \to \mathbb{R}$ be $k$-times differentiable such that all derivatives up to order $k$ are bounded on $\mathbb{R}$. Let $\mathcal{F}$ be the set of all functions $f_w$ defined by (1)–(3) where the weight vector $w$ satisfies

$$\sum_{j=1}^{K_n} |w^{(L)}_{1,1,j}| \leq C, \quad (24)$$

$$|w^{(l)}_{k,i,j}| \leq B \quad (k \in \{1, \ldots, K_n\}, i, j \in \{1, \ldots, r\}, l \in \{1, \ldots, L - 1\}) \quad (25)$$

and

$$|w^{(l)}_{k,i,j}| \leq A \quad (k \in \{1, \ldots, K_n\}, i \in \{1, \ldots, r\}, j \in \{1, \ldots, d\}). \quad (26)$$

Then we have for any $1 \leq p < \infty$, $0 < \epsilon < \beta$ and $x^n_1 \in \mathbb{R}^d$

$$\mathcal{N}_p \left( \epsilon, \{ T_{\beta} f \cdot [\cdot]^{\alpha} : f \in \mathcal{F}, x^n_1 \} \right) \leq \left( c_{10} \cdot \frac{B^{(L - 1) \cdot d \cdot A \cdot (\epsilon / \beta)^{d/k}}{c_{12}} \right).$$  

17
Proof. See Lemma 4 in Drews and Kohler (2022). \(\square\)

The next lemma gives a bound on the error of the approximation of a Lipschitz continuous and bounded function by an over-parametrized deep neural network.

**Lemma 5.** Let \(\sigma\) be the logistic squasher, let \(1 \leq \alpha_n \leq \log n\), let \(m : \mathbb{R}^d \to \mathbb{R}\) be Lipschitz continuous as well as bounded, let \(L, r, n \in \mathbb{N}\) with \(L \geq 2\), \(r \geq 2d\), \(n \geq \exp(r + 1)\), and \(n \geq \exp(r + 1)\) and let \(K, N_n \in \mathbb{N}\) with \(2 \leq K \leq \alpha_n - 1\) and \(N_n \cdot (K^2 + 1)^d \leq K_n\). Given \(u_1, v_1, \ldots, u_{N_n(K^2+1)^d}, v_{N_n(K^2+1)^d} \in [-K - \frac{2}{K}, K]^d\), choose \(\tilde{w}\) such that

\[
w_{k,j,j}^{(0)} = 4d \cdot K^2 \cdot (\log n)^2 \quad \text{and} \quad w_{k,j,0}^{(0)} = -4d \cdot K^2 \cdot (\log n)^2 \cdot u_{k,j}^{(j)} \quad \text{for} \quad j \in \{1, \ldots, d\},
\]

\[
w_{k,j,0}^{(0)} = -4d \cdot K^2 \cdot (\log n)^2 \quad \text{and} \quad w_{k,j,0}^{(0)} = 4d \cdot K^2 \cdot (\log n)^2 \cdot v_{k,j}^{(j)} \quad \text{for} \quad j \in \{1, \ldots, d\},
\]

\[
w_{k,s,t}^{(0)} = 0 \quad \text{if} \quad s \leq 2d, s \neq t, s \neq t + d \quad \text{and} \quad t > 0,
\]

\[
w_{k,1,t}^{(1)} = 8 \cdot (\log n)^2 \quad \text{for} \quad t \in \{1, \ldots, 2d\},
\]

\[
w_{k,1,0}^{(1)} = -8 \cdot (\log n)^2 \left(2d - \frac{1}{n}\right),
\]

\[
w_{k,1,t}^{(1)} = 0 \quad \text{for} \quad t > 2d,
\]

\[
w_{k,1,1}^{(l)} = 6 \cdot (\log n)^2 \quad \text{for} \quad l \in \{2, \ldots, L\},
\]

\[
w_{k,1,0}^{(l)} = -3 \cdot (\log n)^2 \quad \text{for} \quad l \in \{2, \ldots, L\}
\]

and

\[
w_{k,1,t}^{(l)} = 0 \quad \text{for} \quad t > 1 \quad \text{and} \quad l \in \{2, \ldots, L\}
\]

for all \(k \in \{1, \ldots, N_n \cdot (K^2 + 1)^d\}\).

Then there exists \(u_1, v_1, \ldots, u_{N_n(K^2+1)^d}, v_{N_n(K^2+1)^d} \in [-K - \frac{2}{K}, K]^d\) and

\[
\alpha_1, \ldots, \alpha_{N_n(K^2+1)^d} \in \left[-\frac{\|m\|_\infty}{N_n}, \frac{\|m\|_\infty}{N_n}\right]
\]

such that for all pairwise distinct \(j_1, \ldots, j_{N_n(K^2+1)^d} \in \{1, \ldots, K_n\}\)

\[
\int |f_\tilde{w}(x) - m(x)|^2 \mathbf{P}_X(dx) \leq c_{13} \cdot \left(\frac{1}{K} + \frac{N_n^2 \cdot K^{4d}}{n^2} + \left(\frac{K^{2d}}{n} + 1\right)^2 \cdot \mathbf{P}_X(\mathbb{R}^d \setminus [-K, K]^d)\right)
\]

holds for all weight vectors \(\tilde{w}\) which satisfy

\[
\tilde{w}_{1,1,j_1}^{(1)} = \alpha_k \quad (k \in \{1, \ldots, N_n \cdot (K^2 + 1)^d\}), \quad \tilde{w}_{1,1,k}^{(l)} = 0 \quad (k \notin \{j_1, \ldots, j_{N_n(K^2+1)^d}\})
\]

\[
\tilde{w}_{1,1,k}^{(L)} = 0 \quad (k \notin \{j_1, \ldots, j_{N_n(K^2+1)^d}\})
\]
and
\[ |w_{s,k,i}^{(l)} - w_{s,k,i}^{(l)}| \leq \log n \text{ for all } l \in \{0, \ldots, L - 1\}, s \in \{1, \ldots, N_n \cdot (K^2 + 1)^d\}. \] (39)

Additionally we get
\[ \|f_{\bar{w}}\|_\infty \leq c_{14} \cdot \left( 3^d + \frac{(K^2 + 1)^d}{n} \right) \] (40)
where \(c_{14}\) depends on \(\|m\|_\infty\).

**Proof.** Subdivide the cube \([-K - 2\cdot K^2, K]^d\) in \((K^2 + 1)^d\) equidistant cubes \(C_i\) of side length \(2\cdot K\). For simplicity we number these cubes \(C_i\) by \(i \in \{1, \ldots, (K^2 + 1)^d\}\), such that \(C_i\) corresponds to the cube \([u^{(1)}_i, v^{(1)}_i) \times \cdots \times [u^{(d)}_i, v^{(d)}_i)\).

Let \(C_{\text{Lip}}\) be the Lipschitz constant of \(m\).

We apply Lemma 6 from Drews and Kohler (2022) with \(a_i = -K - 2\cdot K^2\), \(b_i = K\) and \(K^2 + 1\) instead of \(K\) to \(m/N_n\) and \(\delta = \frac{1}{K^2}\). This results in
\[ |f_{\bar{w}}(x) - \frac{1}{N_n} \cdot m(x)| \leq c_{15} \cdot \left( \frac{C_{\text{Lip}}}{N_n} \cdot \frac{2}{K} + (K^2 + 1)^d \cdot \frac{1}{n} \right) \]
for all \(x \in [-K - 2\cdot K^2, K]^d\) which are not contained in
\[ A := \bigcup_{i \in \{0,1,\ldots,K^2+1\}} \bigcup_{j \in \{1,\ldots,d\}} \left\{ x \in \mathbb{R}^d : \left| x^{(j)} - \left( -K - \frac{2}{K} + i \cdot \frac{2}{K} \right) \right| < \delta \right\}. \] (41)

We repeat the whole construction \(N_n\) many times. Thus we obtain an approximation \(f_{\bar{w}}\) of
\[ N_n \cdot \frac{1}{N_n} \cdot m(x) \]
which satisfies
\[ |f_{\bar{w}}(x) - m(x)| \leq c_{16} \cdot \left( \frac{1}{K} + N_n \cdot (K^2 + 1)^d \cdot \frac{1}{n} \right) \] (42)
for \(x \notin A\).

Next we shift the grid along the \(j\)-th component so that \([-K, K]^d\) is always covered. This means we modify all \(u^{(j)}_i, v^{(j)}_i\) by the same additional summand which is chosen from the set
\[ \left\{ k \cdot \frac{2}{K^2} : k = 0, 1, \ldots, K - 1 \right\} \]
for fixed \(j \in \{1, \ldots, d\}\). Thus we obtain \(K\) different versions of \(f_{\bar{w}}\) that still satisfy (42) for all \(x \in [-K, K]^d\) up to corresponding versions of \(A\).

Since we shift the grid of cubes we obtain for fixed \(j \in \{1, \ldots, d\}\) \(K\) disjoint versions of \(\bigcup_{i \in \{0,1,\ldots,K^2+1\}} \{ x \in \mathbb{R}^d : \left| x^{(j)} - \left( -K - \frac{2}{K} + i \cdot \frac{2}{K} \right) \right| < \delta \}. \) The sum of \(\mathbf{P}_X\)-measures

19
of these $K$ disjoint sets is less than or equal to one. Therefore at least one of them must have measure less than or equal to $\frac{1}{K}$. Consequently we can shift $u_i$ and $v_i$ so that

$$P_X(A) \leq \sum_{j \in \{1, \ldots, d\}} \frac{1}{K} = \frac{d}{K}$$

holds.

Now we have shown that there exists a shifted version of the grid such that the set $A$ has a measure less than or equal to $\frac{d}{K}$. By inequality (42) we get that $|f_w(x) - m(x)| \leq c_{16} \cdot \left( \frac{1}{K} + \frac{N_n \cdot K^{2d}}{n} \right)$ holds for $x \in [-K, K]^d \setminus A$.

From the second assertion of Lemma 6 in Drews and Kohler (2022) we obtain

$$|f_w(x)| \leq \|m\|_{\infty} \cdot \left( 3^d + (K^2 + 1)^d \cdot \frac{1}{n} \right)$$

for $x \in \mathbb{R}^d$.

Summarizing the above results we get

$$\int |f_w(x) - m(x)|^2 P_X(dx)$$

$$= \int_{[-K, K]^d \setminus A} |f_w(x) - m(x)|^2 P_X(dx) + \int_A |f_w(x) - m(x)|^2 P_X(dx)$$

$$+ \int_{\mathbb{R}^d \setminus [-K, K]^d} |f_w(x) - m(x)|^2 P_X(dx)$$

$$\leq c_{16}^2 \left( \frac{1}{K} + \frac{N_n \cdot K^{2d}}{n} \right)^2 + c_{17} \left( 3^d + \frac{K^{2d}}{n} \right)^2 \cdot \frac{d}{K}$$

$$+ c_{18} \left( 3^d + \frac{K^{2d}}{n} \right)^2 \cdot P_X(\mathbb{R}^d \setminus [-K, K]^d),$$

which implies the assertion.

4.2. Proof of Theorem 1

**Proof.** Let $\epsilon > 0$, $K \in \mathbb{N}$ arbitrary and $N_n = \lceil c_{19} \cdot (\log n)^{18L} \rceil$. Furthermore, let $\tilde{m} : \mathbb{R}^d \to \mathbb{R}$ be a Lipschitz continuous and bounded function such that

$$\int |\tilde{m}(x) - m(x)|^2 P_X(dx) \leq \epsilon. \quad (43)$$

We denote by $A_n$ the event that firstly there exists pairwise disjoint $j_1, \ldots, j_{N_n (K^2 + 1)^d}$ such that the weight vector $w^{(0)}$ satisfies

$$|w^{(0)}_{j_s, k, i} - w^{(l)}_{s, k, i}| \leq \log n \quad \text{for all } l \in \{0, \ldots, L - 1\}, s \in \{1, \ldots, N_n \cdot (K^2 + 1)^d\}$$

and
for some weight vector \( \mathbf{w} \) which satisfies the conditions (27)–(35) of Lemma 5 for \( \tilde{m} \) and that secondly the inequality
\[
\frac{1}{n} \sum_{i=1}^{n} Y_i^2 \leq \beta_n^3
\]
holds.

In case that \( A_n \) holds \( \alpha_k \) is chosen as in Lemma 5 for \( \tilde{m} \), otherwise we set \( \alpha_1 = \ldots = \alpha_{N_n(K^2+1)^d} = 0 \). Then we define the weight vectors \( \mathbf{w}^* \) for given \( \mathbf{w} \) by
\[
(\mathbf{w}^*)^{(l)}_{k,i,j} = \mathbf{w}^{(l)}_{k,i,j} \quad \text{for all } l = 0, \ldots, L - 1,
\]
\[
(\mathbf{w}^*)^{(L)}_{1,1,j} = \alpha_k \quad \text{for all } k = 1, \ldots, N_n \cdot (K^2 + 1)^d,
\]
\[
(\mathbf{w}^*)^{(L)}_{1,1,k} = 0 \quad \text{for all } k \notin \{j_1, \ldots, j_{N_n(K^2+1)^d}\}
\]
and \( (\mathbf{w}^*)^{(0)} \) by
\[
((\mathbf{w}^*)^{(0)})^{(l)}_{k,i,j} = (\mathbf{w}^{(0)})^{(l)}_{k,i,j} \quad \text{for all } l = 0, \ldots, L - 1,
\]
\[
((\mathbf{w}^*)^{(0)})^{(L)}_{1,1,j} = \alpha_k \quad \text{for all } k = 1, \ldots, N_n \cdot (K^2 + 1)^d,
\]
\[
((\mathbf{w}^*)^{(0)})^{(L)}_{1,1,k} = 0 \quad \text{for all } k \notin \{j_1, \ldots, j_{N_n(K^2+1)^d}\}.
\]

In the first step of the proof we start by decomposing the \( L_2 \) error of \( m_n \) in a sum of several terms. We have
\[
\int |m_n(x) - m(x)|^2 \mathbf{P}_X(dx)
\]
\[
= (\mathbf{E}\{ |m_n(X) - Y|\mathbf{P}_D \}) - \mathbf{E}\{ |m(X) - Y|\mathbf{P}_D \}) \cdot 1_{A_n}
\]
\[
+ \int |m_n(x) - m(x)|^2 \mathbf{P}_X(dx) \cdot 1_{A_n^c}
\]
\[
= (\mathbf{E}\{ |m_n(X) - Y|\mathbf{P}_D \}) - (1 + \epsilon) \cdot \mathbf{E}\{ |m_n(X) - T_{\beta_n}Y|\mathbf{P}_D \}) \cdot 1_{A_n}
\]
\[
+ (1 + \epsilon) \cdot \mathbf{E}\{ |m_n(X) - T_{\beta_n}Y|\mathbf{P}_D \}) - (1 + \epsilon) \cdot \frac{1}{n} \sum_{i=1}^{n} |m_n(X_i) - T_{\beta_n}Y_i|^2 \cdot 1_{A_n}
\]
\[
+ (1 + \epsilon) \cdot \frac{1}{n} \sum_{i=1}^{n} |m_n(X_i) - T_{\beta_n}Y_i|^2 - (1 + \epsilon) \cdot \frac{1}{n} \sum_{i=1}^{n} |f_{\mathbf{w}(\tilde{m})}(X_i) - Y_i|^2 \cdot 1_{A_n}
\]
\[
+ (1 + \epsilon) \cdot \frac{1}{n} \sum_{i=1}^{n} |f_{\mathbf{w}(\tilde{m})}(X_i) - T_{\beta_n}Y_i|^2 - (1 + \epsilon) \cdot \frac{1}{n} \sum_{i=1}^{n} |f_{\mathbf{w}(\tilde{m})}(X_i) - Y_i|^2 \cdot 1_{A_n}
\]
\[
+ (1 + \epsilon)^2 \cdot \frac{1}{n} \sum_{i=1}^{n} |f_{\mathbf{w}(\tilde{m})}(X_i) - Y_i|^2 - \mathbf{E}\{ |m(X) - Y|\mathbf{P}_D \}) \cdot 1_{A_n}
\]
\[
+ \int |m_n(x) - m(x)|^2 \mathbf{P}_X(dx) \cdot 1_{A_n^c}
\]

21
In the second step of the proof we show \( \limsup_{n \to \infty} E T_{j,n} \leq 0 \) for \( j \in \{1, 4\} \).

By using \( (a + b)^2 \leq (1 + \epsilon) \cdot a^2 + (1 + \frac{1}{\epsilon}) \cdot b^2 \) for \( a, b \in \mathbb{R} \) we obtain

\[
ET_{1,n} \leq \left(1 + \frac{1}{\epsilon}\right) \cdot E\{|T_{\beta_n}Y - Y|^2\}
\]

and

\[
ET_{4,n} \leq (1 + \epsilon) \cdot \left(1 + \frac{1}{\epsilon}\right) \cdot E\{|T_{\beta_n}Y - Y|^2\}.
\]

Together with \( \beta_n \to \infty \) \( (n \to \infty) \) and \( EY^2 < \infty \) this implies the assertion of the second step.

In the third step of the proof we show

\[
\limsup_{n \to \infty} E T_{3,n} \leq 0.
\]

If \( |y| \leq \beta_n \) then it holds

\[
|T_{\beta_n}z - y| \leq |z - y|
\]

for any \( z \in \mathbb{R} \). This implies

\[
\frac{1}{n} \sum_{i=1}^{n} |m_n(X_i) - T_{\beta_n}Y_i|^2 = \frac{1}{n} \sum_{i=1}^{n} |T_{\beta_n}f_{wn} (X_i) - T_{\beta_n}Y_i|^2
\]

\[
\leq \frac{1}{n} \sum_{i=1}^{n} |f_{wn} (X_i) - T_{\beta_n}Y_i|^2.
\]

Thus the assertion of the third step holds.

In the fourth step of the proof we show that the assumptions (12) - (14) of Lemma 1 are satisfied which means that

\[
\| \nabla_{w} F(w) \| \leq L_n
\]

for all \( w \in S := \left\{ v : \|v - w(0)\| \leq 2 \cdot \sqrt{F(w(0))} + 1 \right\} \),

\[
\| \nabla_{w} F(w) - \nabla_{\tilde{w}} F(\tilde{w}) \| \leq L_n \cdot \|w - \tilde{w}\|
\]

for all \( w, \tilde{w} \in S \)

\[
|F(w^*) - F((w^*)^{(0)})| \leq D_n \cdot \|((w^*)^{(L)})_{k=1,...,K_n} \| \cdot \|((w^{(l)})_{i,j,k,l;l \leq L} - ((w^{(0)})^{(l)})_{i,j,k,l;l \leq L} \|
\]

22
for all
\[(w^{(l)}_{i,j,k})_{i,j,k,l:L} \in \tilde{S}\]
\[:= \left\{ (w^{(l)}_{i,j,k})_{i,j,k,l:L} : \left\| (w^{(0)}_{i,j,k})_{i,j,k,l:L} \right\| \leq \sqrt{2 \cdot F(w^{(0)})} \right\}\]
hold, if \(A_n\) holds.
If \(A_n\) holds, then we have
\[F_n(w^{(0)}) = \frac{1}{n} \sum_{i=1}^{n} y_i^2 \leq \beta^3_n.\]

Let \(w \in S\). Then we can conclude that
\[\left\| (w^{(l)}_{i,j,k})_{i,j,k,l:L} \right\|_\infty \leq \left\| w - w^{(0)} \right\|_\infty + \left\| (w^{(0)}_{i,j,k})_{i,j,k,l:L} \right\|_\infty \]
\[- \leq 2 \cdot \sqrt{F_n(w^{(0)})} + 1 + c_{20} \cdot (\log n)^2 \]
\[- \leq c_21 \cdot (\log n)^2 \]
and
\[\left\| (w^{(L)}_{1,1,k})_{k=1,...,K_n} \right\|_\infty \leq \left\| w - w^{(0)} \right\|_\infty + \left\| (w^{(0)}_{1,1,k})_{k=1,...,K_n} \right\|_\infty \]
\[- \leq 2 \cdot \sqrt{F_n(w^{(0)})} + 1 \]
\[- \leq c_22 \cdot (\log n)^{3/2}.\]

Hence (18)-(23) are satisfied for \(B_n = c_21 \cdot (\log n)^2\) and \(\gamma^*_n = c_22 \cdot (\log n)^{3/2}\). By Lemma 2 and Lemma 3 we get for \(\alpha_n = c_{23}\) that (12) and (13) are satisfied provided that \(L_n \geq K_3^{3/2} \cdot (\log n)^{6L+5}\).

It remains to show that (14) holds. Let \(w\) such that \((w^{(l)}_{i,j,k})_{i,j,k,l:L} \in \tilde{S}\). Then we have
\[|F_n(w^*) - F_n((w^*)^{(0)})|\]
\[= \left| \frac{1}{n} \sum_{i=1}^{n} (f_{w^*}(X_i) - Y_i)^2 - \frac{1}{n} \sum_{i=1}^{n} (f_{(w^*)^{(0)}}(X_i) - Y_i)^2 \right|\]
\[= \left( \frac{1}{n} \sum_{i=1}^{n} (f_{w^*}(X_i) - Y_i + f_{(w^*)^{(0)}}(X_i) - Y_i) \left( f_{w^*}(X_i) - f_{(w^*)^{(0)}}(X_i) \right) \right)^{1/2}\]
\[\leq \left( \frac{1}{n} \sum_{i=1}^{n} (f_{w^*}(X_i) - Y_i + f_{(w^*)^{(0)}}(X_i) - Y_i \right)^2 \right)^{1/2} \cdot \left( \frac{1}{n} \sum_{i=1}^{n} \left( f_{w^*}(X_i) - f_{(w^*)^{(0)}}(X_i) \right)^2 \right)^{1/2}\]
\[
\begin{aligned}
&\leq \left( \frac{2}{n} \sum_{i=1}^{n} \left( f_{w^*}(X_i) + f_{(w^*)^{(0)}}(X_i) \right)^2 + \frac{8}{n} \sum_{i=1}^{n} Y_i^2 \right)^{1/2} \\
&\quad \cdot \left( \frac{1}{n} \sum_{i=1}^{n} \left( \sum_{k=1}^{K_n} (w^*)_{1,1,k}^{(L)} \right)^2 \cdot \sum_{k=1}^{K_n} \left| f_{(w^*)^{(0)},k,1}^{(L)}(X_i) - f_{(w^*)^{(0)},k,1}^{(L)}(X_i) \right|^2 \right)^{1/2}.
\end{aligned}
\]

For the first term we get
\[
\begin{aligned}
&\leq \left( \frac{2}{n} \sum_{i=1}^{n} \left( f_{(w^*)^{(0)}}(X_i) \right)^2 + \frac{8}{n} \sum_{i=1}^{n} Y_i^2 \right)^{1/2} \\
&\quad \leq \left( \frac{2}{n} \sum_{i=1}^{n} 2 \cdot \left( f_{(w^*)^{(0)}}(X_i) \right)^2 + \frac{8}{n} \sum_{i=1}^{n} Y_i^2 \right)^{1/2} \\
&\quad \leq \left( 4 \cdot \frac{1}{n} \sum_{i=1}^{n} \left( \sum_{k=1}^{K_n} (w^*)_{1,1,k}^{(L)} \right)^2 \cdot \sum_{k=1}^{K_n} \left| f_{(w^*)^{(0)},k,1}^{(L)}(X_i) \right|^2 \\
&\quad \quad + 16 \cdot \frac{1}{n} \sum_{i=1}^{n} f_{(w^*)^{(0)}}(X_i)^2 + \frac{8}{n} \sum_{i=1}^{n} Y_i^2 \right)^{1/2} \\
&\quad \leq \left( 4 \cdot \max_{i=1,\ldots,n} \sum_{k=1}^{K_n} \left| f_{(w^*)^{(0)},k,1}^{(L)}(X_i) \right|^2 \\
&\quad \quad + 16 \cdot \frac{1}{n} \sum_{i=1}^{n} f_{(w^*)^{(0)}}(X_i)^2 + \frac{8}{n} \sum_{i=1}^{n} Y_i^2 \right)^{1/2}.
\end{aligned}
\]

By Lemma 5 for \( \bar{m} \) we get \( |\alpha_k| \leq \frac{c_4}{\bar{m}} \) and
\[
\hat{f}_{(w^*)^{(0)}}(X_i) \leq c_{25} \cdot \left( 3^d + \left( \frac{K^2 + 1}{\bar{m}} \right)^d \right).
\]

From the proof of Lemma 2 we know that
\[
|f_{(w^*)^{(0)},k,1}(x) - f_{(w^*)^{(0)},k,1}(x)| \\
\leq c_{26} \cdot \left( \log n \right)^{2L} \cdot \max_{i,j,k,s \leq L} \left| (w^*)_{k,i,j}^{(s)} - ((w^*)^{(0)})_{k,i,j}^{(s)} \right|
\]
holds. Therefore we obtain for \( (w_{i,j,k}^{(L)})_{i,j,k,l \leq L} \in \tilde{S} \)
\[
\max_{i=1,\ldots,n} \sum_{k=1}^{K_n} \left| f_{(w^*)^{(0)},k,1}^{(L)}(X_i) \right|^2
\]

24
\[
\leq c_{27} \cdot (\log n)^{4L} \cdot \sum_{k=1}^{K_n} \max_{i,j,s:s<s<L} |(w^*)_{k,i,j}^{(s)} - ((w^*)_{k,i,j})^{(0)}| \\
\leq c_{27} \cdot (\log n)^{4L} \cdot \| (w_{i,j,k}^{(l)})_{i,j,k,l<l<L} - ((w^0)_{i,j,k,l<l<L}) \| \\
\leq c_{27} \cdot (\log n)^{4L+3}.
\]

From this together with the definition of \( w^* \) we can conclude
\[
\left( \frac{2}{n} \sum_{i=1}^{n} \left( f_{w^*}^L(X_i) + f_{(w^*)^{(0)}}(X_i) \right)^2 + \frac{8}{n} \sum_{i=1}^{n} Y_i^2 \right)^{1/2} \\
\leq \left( 4 \cdot \sum_{k=1}^{K_n} \left( (w^*)_{1,1,k}^{(L)} \right)^2 \cdot c_{27} \cdot (\log n)^{4L+3} + 16 \cdot \frac{1}{n} \sum_{i=1}^{n} f_{(w^*)^{(0)}}(X_i)^2 + \frac{8}{n} \sum_{i=1}^{n} Y_i^2 \right)^{1/2} \\
\leq \left( c_{28} \cdot \frac{N_n \cdot (K^2 + 1)^d}{N_n^2} \cdot (\log n)^{4L+3} + \left( c_{29} \cdot \left( 3^d + \frac{(K^2 + 1)^d}{n} \right) \right)^2 + 8 \cdot c_{31}^3 \cdot (\log n)^3 \right)^{1/2} \\
\leq c_{30} \left( \frac{(K^2 + 1)^d}{N_n} \cdot (\log n)^{4L+3} + \left( \frac{(K^2 + 1)^d}{n} \right)^2 + (\log n)^3 \right)^{1/2}.
\]

Furthermore, due to (44) we have
\[
\left( \frac{1}{n} \sum_{i=1}^{n} \left( \sum_{k=1}^{K_n} \left( (w^*)_{1,1,k}^{(L)} \right)^2 \cdot \sum_{k=1}^{K_n} \left| f_{w^*,k,1}^L(X_i) - f_{(w^*)^{(0)},k,1}(X_i) \right|^2 \right) \right)^{1/2} \\
\leq \left( \sum_{k=1}^{K_n} \left( (w^*)_{1,1,k}^{(L)} \right)^2 \cdot \sum_{i=1}^{n} \max_{k=1,n} \left| f_{w^*,k,1}^L(X_i) - f_{(w^*)^{(0)},k,1}(X_i) \right|^2 \right)^{1/2} \\
\leq \| (w_{i,j,k}^{(l)})_{k=1,...,K_n} \| \cdot \| (w^0)_{i,j,k,l<l<l} \|. \\
\]

This yields
\[
|F_n((w^*)^{(l)}) - F_n((w^*)^{(0)})| \\
\leq c_{32} \left( \frac{(K^2 + 1)^{d/2}}{N_n^{1/2}} \cdot (\log n)^{4L+3/2} + \frac{(K^2 + 1)^d \cdot (\log n)^{2L}}{n} + (\log n)^{2L+3/2} \right) \\
\cdot \| (w_{i,j,k}^{(l)})_{k=1,...,K_n} \| \cdot \| (w^0)_{i,j,k,l<l<l} \|. \\
\]

Thus (44) is satisfied with
\[
D_n = c_{32} \cdot (\log n)^{2L} \cdot \left( \frac{(K^2 + 1)^{d/2}}{N_n^{1/2}} \cdot (\log n)^{2L+3/2} + \frac{(K^2 + 1)^d}{n} + (\log n)^{3/2} \right). \\
\]

For \( n \) large we get
\[
D_n \leq c_{33} \cdot (\log n)^{4L+2}.
\]
In the fifth step of the proof we show
\[ \mathbb{P}(A_n^c) \leq \frac{c_{34}}{(\log n)^3}. \]

To show this, we first bound the probability that the weight vector \( \mathbf{w}^{(0)} \) does not satisfy the first condition of the event \( A_n \). For this, we consider a sequential choice of weights in the \( K_n \) fully connected neural networks. Each of these \( K_n \) fully connected neural networks contains \((r+1) + (L-2) \cdot r \cdot (r+1) + r \cdot (d+1)\) weights. Therefore, the probability that all these weights never satisfy condition (39) for \( s = 1 \) is bounded from below by
\[
\left( \frac{\log n}{40d \cdot (\log n)^2} \right)^{(r+1)+(L-2) \cdot r \cdot (r+1)} \cdot \left( \frac{\log n}{16d \cdot (\log n)^2 \cdot n^\tau} \right)^{r \cdot (d+1)}.
\]

Consequently, the probability that this condition is never satisfied in the first \( nr^{(d+1)\tau+1} \) many fully connected neural networks for \( j_1 \) is for large \( n \) bounded from above by
\[
\left( 1 - \frac{1}{40d \cdot \log n} \right)^{(r+1)+(L-2) \cdot r \cdot (r+1)} \cdot \left( \frac{1}{16d \cdot \log n \cdot n^\tau} \right)^{r \cdot (d+1)} \cdot n^{r \cdot (d+1)\tau+1} \leq \left( 1 - n^{-r(d+1)\tau-0.5} \right)^{lr \cdot (d+1)\tau+1}.
\]

Because of condition (6) we have \( K_n \geq N_n \cdot (K^2 + 1)^d \cdot nr^{(d+1)\tau+1} \) for large \( n \). This implies that for large \( n \) condition (39) is satisfied outside of an event of probability
\[
N_n \cdot (K^2 + 1)^d \cdot \left( 1 - n^{-r(d+1)\tau-0.5} \right)^{nr^{(d+1)\tau+1}} \leq N_n \cdot (K^2 + 1)^d \cdot \left( \exp \left( -n^{-r(d+1)\tau-0.5} \right) \right) n^{r \cdot (d+1)\tau+1} \leq N_n \cdot (K^2 + 1)^d \cdot \exp \left( -n^{0.5} \right) \leq n^\kappa \cdot \exp \left( -n^{0.5} \right) \leq \frac{c_{35}}{n}.
\]

Then we obtain for large \( n \) by Markov’s inequality
\[
\mathbb{P}(A^c) \leq \frac{c_{35}}{n} + \mathbb{P}\left\{ \frac{1}{n} \sum_{i=1}^{n} Y_i^2 > \beta_n^3 \right\} \leq \frac{c_{35}}{n} + \mathbb{E}\left( \frac{1}{n} \sum_{i=1}^{n} Y_i^2 \right) \leq \frac{c_{35}}{n} + \frac{\mathbb{E}(Y^2)}{\beta_n^3}.
\]
where the last inequality holds since $EY^2 < \infty$.

In the sixth step of the proof we show

$$\limsup_{n \to \infty} ET_{2,n} \leq 0.$$ 

We have

$$\frac{1}{1 + \epsilon} \cdot E \{ T_{2,n} \} \leq \int_0^{4.2} \mathbf{P} \left\{ \left( E \{ |m_n(X) - T_{\beta_n} Y|^2 |D_n \} \right) \\
- \frac{1}{n} \sum_{i=1}^{n} |m_n(X_i) - T_{\beta_n} Y_i|^2 \cdot 1_{A_n > t} \right\} dt \\
\leq n^{-1/2} + \int_n^{4.2} \mathbf{P} \left\{ \left( E \{ |m_n(X) - T_{\beta_n} Y|^2 |D_n \} \right) \\
- \frac{1}{n} \sum_{i=1}^{n} |m_n(X_i) - T_{\beta_n} Y_i|^2 \cdot 1_{A_n > t} \right\} dt.$$ 

W.l.o.g. we can assume that $A_n$ holds. Hence, by Lemma 1, it follows that

$$\|((w^{(t_n)}_{L,1,k}))_{i,j,k,l:1 \leq l < L} - ((w^{(0)}_{L,1,k}))_{i,j,k,l:1 \leq l < L}\| \leq c_{37} \cdot (\log n)^{3/2}$$

and

$$\|((w^{(t_n)}_{L,1,k}))_{k=1,...,K_n}\| \leq c_{38} \cdot (\log n)^{3/2},$$

hold. Consequently, we obtain

$$\|((w^{(t_n)}_{i,j,k,l:1 \leq l < L}))_{i,j,k,l:1 \leq l < L}\| \infty \\
\leq \|((w^{(t_n)}_{i,j,k,l:1 \leq l < L}))_{i,j,k,l:1 \leq l < L}\| \infty + \|((w^{(0)}_{i,j,k,l:1 \leq l < L}))_{i,j,k,l:1 \leq l < L}\| \infty \\
\leq c_{37} \cdot (\log n)^{3/2} + c_{39} \cdot (\log n)^2$$

and

$$\|((w^{(t_n)}_{i,j,k,0}))_{i,j,k}\| \infty \\
\leq \|((w^{(t_n)}_{i,j,k,0}))_{i,j,k} - ((w^{(0)}_{i,j,k,0}))_{i,j,k}\| \infty + \|((w^{(0)}_{i,j,k,0}))_{i,j,k}\| \infty \\
\leq c_{38} \cdot (\log n)^{3/2} + c_{40} \cdot (\log n)^2 \cdot n^r.$$ 

This implies that $m_n$ is contained in the function space

$$\{T_{\beta_n} f : f \in \mathcal{F}\}$$

27
where $\mathcal{F}$ is defined as in Lemma 2.4 with $C = c_{41} \cdot K_n \cdot (\log n)^{3/2}$, $B = c_{42} \cdot (\log n)^2$ and $A = c_{43} \cdot (\log n)^2 \cdot n^\tau$. Thus, with Lemma 2.4 and standard bounds of empirical process theory (cf., Theorem 9.1 in Györfi et al. (2002)), it follows

$$
P \left\{ \left( \mathbb{E} \left\{ |m_n(X) - T_{\beta_n} Y_i^2(X)| \right\} \right) - \frac{1}{n} \sum_{i=1}^n \left| m_n(X_i) - T_{\beta_n} Y_i^2 \right| \cdot 1_{A_n} > t \right\}$$

$$\leq 8 \cdot \left( c_{44} \cdot \frac{\beta_n^{\tau t/8}}{t/8} \right) \cdot (c_{45} \cdot (\log n)^{\tau t/8} \cdot \left( \frac{c_{47} \cdot K_n \cdot (\log n)^{3/2}}{t/8} \right)^{d/k}) + c_{48} \cdot \exp \left( - \frac{n \cdot t^2}{256 \cdot \beta_n^4} \right).
$$

Using (5) and $\tau = \frac{1}{d+1}$ we get for $k > (\kappa + 1) \cdot d \cdot (d + 1) \cdot (d + 2)$ and $t > n \frac{1}{2(d+2)}$ that the left hand side above is for $n$ large enough less than or equal to

$$8 \cdot \left( c_{44} \cdot \frac{\beta_n^{\tau t/8}}{t/8} \right) \cdot (c_{45} \cdot (\log n)^{\tau t/8} \cdot \left( \frac{c_{47} \cdot K_n \cdot (\log n)^{3/2}}{t/8} \right)^{d/k}) + c_{48} \cdot \exp \left( - \frac{n \cdot t^2}{256 \cdot \beta_n^4} \right)
$$

$$\leq \exp \left( c_{49} \cdot (\log n)^{\tau t/8} \cdot d^{\tau t/8} \cdot \log \left( c_{44} \cdot \frac{\beta_n^{\tau t/8}}{t/8} \right) \right) \cdot \exp \left( - \frac{n \cdot t^2}{256 \cdot \beta_n^4} \right)
$$

$$\leq \exp \left( c_{50} \cdot \left( (\log n)^{\frac{1}{2(d+1)} + (\kappa + 1) \frac{d}{2(d+2)}} - \frac{n \frac{2(d+3)}{2(d+2)}}{(\log n)^4} \right) \right) \cdot \exp \left( - \frac{n \cdot t^2}{256 \cdot \beta_n^4} \right)
$$

$$\leq \exp \left( c_{50} \cdot \left( (\log n)^{\frac{1}{2(d+1)} + \frac{d}{2(d+2)}} - \frac{n \frac{2(d+3)}{2(d+2)}}{(\log n)^4} \right) \right) \cdot \exp \left( - \frac{n \cdot t^2}{256 \cdot \beta_n^4} \right)
$$

$$= \exp \left( c_{50} \cdot \frac{d}{2(d+2)} \cdot \left( (\log n)^{\frac{1}{2(d+1)} + \frac{d}{2(d+2)}} - \frac{n \frac{2(d+3)}{2(d+2)}}{(\log n)^4} \right) \right) \cdot \exp \left( - \frac{n \cdot t^2}{256 \cdot \beta_n^4} \right)
$$

$$\leq c_{52} \cdot \exp \left( - \frac{n \cdot t^2}{256 \cdot \beta_n^4} \right)
$$

$$\leq c_{53} \cdot \exp \left( - \frac{n \frac{2(d+3)}{2(d+2)}}{(\log n)^4} \right)
$$

holds. Therefore, we obtain

$$\mathbb{E} \left\{ T_{2,n} \right\} \leq (1 + \epsilon) \cdot \left( n^{\frac{1}{2(d+2)}} + 4 \beta_n^2 \cdot c_{54} \cdot \exp \left( - \frac{n \frac{2(d+3)}{2(d+2)}}{(\log n)^4} \right) \right) \rightarrow 0 \quad (n \rightarrow \infty).$$

In the seventh step of the proof we show

$$\lim_{n \rightarrow \infty} \mathbb{E} \left\{ T_{6,n} \right\} \leq 0.$$
Due to the assertion of the fifth step together with the integrability of \( m \) we get

\[
E\{T_{6,n}\} \leq \left( 2 \cdot \int |m(x)|^2 \, P_X(dx) + 2 \cdot \int |m(x)|^2 \, P_X(dx) \right) \cdot P(A_n^c)
\]

\[
\leq 2 \cdot (\beta_n^2 + c_{55}) \cdot \frac{c_{36}}{(\log n)^3}.
\]

This implies the assertion of the seventh step.

In the eighth step of the proof we bound

\[
ET_{5,n}.
\]

If \( A_n \) holds, then as shown in step four, we can apply Lemma 1 with

\[
D_n \leq c_{35} \cdot (\log n)^{4L+2}.
\]

This together with the definition of \( w^* \) and \( (w^*)^{(0)} \) yields

\[
\frac{1}{n} \sum_{i=1}^{n} |f_{w(t_n)}(X_i) - Y_i|^2 = F_n \left( w^{(t_n)} \right)
\]

\[
\leq F_n \left( (w^*)^{(0)} \right) + D_n \cdot \| (w^*)^{(L)}_{1,1,k} k=1,\ldots,K_n \| \cdot \sqrt{2 \cdot F_n \left( (w^*)^{(0)} \right)}
\]

\[
+ \frac{\| (w^*)^{(L)}_{1,1,k} k=1,\ldots,K_n - (w^{(0)})^{(L)}_{1,1,k} k=1,\ldots,K_n \|^2}{2}
\]

\[
\leq F_n \left( (w^*)^{(0)} \right) + c_{56} \cdot (\log n)^{4L+2} \cdot \frac{N_n^{1/2} \cdot (K^2 + 1)^{d/2}}{N_n} \cdot (\log n)^{3/2}
\]

\[
+ \frac{N_n \cdot (K^2 + 1)^d}{2 \cdot N_n^2} + \frac{c_{37} \cdot (\log n)^3}{t_n}
\]

\[
\leq F_n \left( (w^*)^{(0)} \right) + c_{57} \cdot \frac{(K^2 + 1)^d}{N_n^{1/2}} \cdot (\log n)^{4L+4}.
\]

Thus we obtain

\[
E \{ T_{5,n} \}
\]

\[
= (1 + \epsilon)^2 \cdot E \left\{ \left( F_n \left( w^{(t_n)} \right) - E\{ |m(X) - Y|^2 \} \right) \cdot 1_{A_n} \right\}
\]

\[
+ (1 + \epsilon)^2 \cdot E \{ |m(X) - Y|^2 \} \cdot 1_{A_n}
\]

\[
\leq (1 + \epsilon)^2 \cdot \left( E \left\{ F_n \left( (w^*)^{(0)} \right) \cdot 1_{A_n} c_{57} \left( \frac{(K^2 + 1)^d}{N_n^{1/2}} \cdot (\log n)^{4L+4} \right) \cdot 1_{A_n} \right\}
\]

\[
- E\{ |m(X) - Y|^2 \} \cdot P(A_n) \right) + ((1 + \epsilon)^2 - 1) \cdot E\{ |m(X) - Y|^2 \}.
\]

Let \( \hat{A}_n \) be the event where the weight vector \( w^{(0)} \) satisfies

\[
(|w^{(0)})^{(l)}_{j,s,k,i} - w^{(l)}_{j,s,k,i}| \leq \log n \quad \text{for all } l \in \{0, \ldots, L-1\}, s \in \{1, \ldots, N_n \cdot (K^2 + 1)^d \}
\]
for some weight vector \( \mathbf{w} \) which satisfies conditions (27)–(35) of Lemma 5 for \( \bar{m} \). Then we get from the fifth step of the proof

\[
P(\bar{A}_n) - P(A_n) \leq P\left( \frac{1}{n} \sum_{i=1}^{n} Y_i^2 > \beta_n^3 \right) \leq \frac{c_{58}}{(\log n)^2}.
\]

This together with the fact that \((X_1, Y_1), \ldots, (X_n, Y_n)\) are independent of \(\bar{A}_n\) yields

\[
E\{ F_n((\mathbf{w}^*)^{(0)}) \cdot 1_{\bar{A}_n} \} - E\{ |m(X) - Y|^2 \} \cdot P(A_n)
\]

\[
\leq E\left\{ \frac{1}{n} \sum_{i=1}^{n} |f((\mathbf{w}^*)^{(0)})(X_i) - Y_i|^2 \cdot 1_{\bar{A}_n} \right\} - E\{ |m(X) - Y|^2 \} \cdot P(A_n)
\]

\[
+ E\{ |m(X) - Y|^2 \} \cdot (P(\bar{A}_n) - P(A_n))
\]

\[
\leq E\left\{ \frac{1}{n} \sum_{i=1}^{n} |f((\mathbf{w}^*)^{(0)})(X_i) - Y_i|^2 |(\mathbf{w}^*)^{(0)} \right\} - E\{ |m(X) - Y|^2 \} \cdot 1_{\bar{A}_n}
\]

\[
+ \frac{c_{59}}{(\log n)^3}
\]

\[
= E\left\{ \left( \frac{1}{n} \sum_{i=1}^{n} |f((\mathbf{w}^*)^{(0)})(X_i) - Y_i|^2 |(\mathbf{w}^*)^{(0)} \right) - E\{ |m(X) - Y|^2 \} \right\} \cdot 1_{\bar{A}_n}
\]

\[
+ \frac{c_{59}}{(\log n)^3}
\]

\[
\leq E\left\{ \int |f((\mathbf{w}^*)^{(0)})(x) - m(x)|^2 P_X(dx) \cdot 1_{\bar{A}_n} \right\} + \frac{c_{59}}{(\log n)^3}.
\]

Because of the choice of \( \bar{m} \) and Lemma 5 we get for \( K \) such large that \( supp(X) \subseteq [-K, K]^d \)

\[
E\left\{ \int |f((\mathbf{w}^*)^{(0)})(x) - m(x)|^2 P_X(dx) \cdot 1_{\bar{A}_n} \right\}
\]

\[
\leq 2 \cdot E\left\{ \int |f((\mathbf{w}^*)^{(0)})(x) - \bar{m}(x)|^2 P_X(dx) \cdot 1_{\bar{A}_n} \right\} + 2 \int |\bar{m}(x) - m(x)|^2 P_X(dx)
\]

\[
\leq c_{60} \cdot \left( \frac{1}{K} + \frac{N_d^2 \cdot K^{4d}}{n^2} + \left( \frac{K^{2d}}{n} + 1 \right)^2 \cdot P_X(\mathbb{R}^d \setminus [-K, K]^d) \right) + 2\epsilon
\]

\[
\leq c_{61} \cdot \left( \frac{1}{K} + \frac{N_d^2 \cdot K^{4d}}{n^2} \right) + 2\epsilon.
\]

Due to the definition of \( N_n \) we obtain

\[
\frac{(K^2 + 1)^d}{N_n^{1/2}} \cdot (\log n)^{4L+4} \to 0 \quad (n \to \infty).
\]

Summarizing the above results yields

\[
\limsup_{n \to \infty} E\{ T_{5,n} \} \leq c_{62} \cdot (1 + \epsilon)^2 \cdot \left( \frac{1}{K} + 2\epsilon \right) + ((1 + \epsilon)^2 - 1) \cdot E\{ |m(X) - Y|^2 \}.
\]
In the ninth step of the proof we finish the proof of Theorem 1. The results of steps 1, 2, 3, 6, 7 and 8 imply for \( K \to \infty \)
\[
\limsup_{n \to \infty} \mathbb{E} \int |m_n(x) - m(x)|^2 \mathbb{P}(dx) \\
\leq c_63 \cdot ((1 + \epsilon)^2 \cdot 2\epsilon + ((1 + \epsilon)^2 - 1) \cdot \mathbb{E}\{|m(X) - Y|^2\}).
\]
With \( \epsilon \to 0 \) we get the assertion. \( \square \)

### 4.3. Auxiliary results for the proof of Theorem 2

The following theorem is crucial for proving Theorem 2 and Theorem 3. It is needed to analyze the rate of convergence of the over-parametrized deep neural network estimate.

**Theorem 4.** Let \( n \in \mathbb{N} \) with \( n \geq 2 \), let \((X, Y), (X_1, Y_1), \ldots, (X_n, Y_n)\) be independent and identically distributed \( \mathbb{R}^d \times \mathbb{R} \)-valued random variables such that \( \operatorname{supp}(X) \) is bounded, that \( \mathbb{E}\{e^{c_3 \cdot Y^2}\} < \infty \) holds and that the corresponding regression function \( m(x) = \mathbb{E}\{Y|X = x\} \) is bounded. Let \( \sigma(x) = 1/(1+e^{-x}) \) be the logistic squasher, let \( K_n, L, r, t_n \in \mathbb{N}, M_n \geq 1 \) and \( \lambda_n, \tau > 0 \). Let \( \tilde{K}_n \in \{1, \ldots, K_n\} \),
\[
w_{k,i,j}^{(l)} \in [-20d \cdot (\log n)^2, 20d \cdot (\log n)^2] \quad \text{for } l = 1, \ldots, L, k = 1, \ldots, \tilde{K}_n
\]
and
\[
w_{k,i,j}^{(0)} \in [-8d \cdot (\log n)^2 \cdot n^\tau, 8d \cdot (\log n)^2 \cdot n^\tau] \quad \text{for } k = 1, \ldots, \tilde{K}_n.
\]
Assume that
\[
\sqrt{\sum_{k=1}^{\tilde{K}_n} |w_{1,1,k}^{(L)}|^2} \leq M_n,
\]
and that
\[
\left| \sum_{k=1}^{\tilde{K}_n} w_{1,1,k}^{(L)} \cdot f_{\tilde{w}_{k,1}}^{(L)}(x) \right| \leq \beta_n
\]
holds for \( x \in \operatorname{supp}(X) \) and for all \( \tilde{w} \) which satisfy
\[
|\tilde{w}_{i,j,k}^{(l)} - w_{i,j,k}^{(l)}| \leq \log n \quad \text{for } l = 0, \ldots, L - 1.
\]
Assume furthermore
\[
\frac{K_n}{n^\kappa} \to 0 \quad (n \to \infty)
\]
for some $\kappa > 0$,

$$\frac{K_n}{K_n \cdot n^{-(d+1)\rho + 1}} \to \infty \quad (n \to \infty) \tag{49}$$

Define the estimate $m_n$ as in Section 2 with

$$\lambda_n = \frac{1}{t_n} \quad \text{and} \quad t_n = [c_{64} \cdot L_n] \tag{50}$$

for some $c_{64} \geq 1$ and for some $L_n > 0$ which satisfies

$$L_n \geq K_n^{3/2} \cdot (\log n)^{6L+2},$$

and assume

$$c_1 \cdot c_3 \geq 2. \tag{51}$$

Then we have for any $\epsilon > 0$

$$\mathbb{E} \int |m_n(x) - m(x)|^2 \mathbb{P}_X(dx) \leq c_{65} \cdot \left( \frac{n^{\tau d + \epsilon}}{n} + M_n^2 \cdot (\log n)^{4L+3/2} \right)$$

$$+ \sup_{\left|w_{i, j, k}^{(l)} - w_{i, j, k}^{(0)}\right| \leq \log n} \left| \frac{1}{K_n} \int \left| \sum_{k=1}^{K_n} w_{1,1,k}^{(L)} \cdot f_{\tilde{w},1,k}^{(L)}(x) - m(x) \right|^2 \mathbb{P}_X(dx) \right|. \tag{52}$$

Proof. Let $A_n$ be the event that firstly the weight vector $w^{(0)}$ satisfies

$$\left| (w^{(0)})_{j, s, l}^{(l)} - (w^{(l)})_{j, s, l}^{(l)} \right| \leq \log n \quad \text{for all } l \in \{0, \ldots, L-1\}, s \in \{1, \ldots, \tilde{K}_n\}$$

for some pairwise distinct $j_1, \ldots, j_{\tilde{K}_n} \in \{1, \ldots, K_n\}$ and that secondly

$$\max_{i=1, \ldots, n} |Y_i| \leq \sqrt{\beta_n}$$

holds. Then we define the weight vectors $w^*$ for given $\tilde{w}$ by

$$(w^*)_{k, i, j}^{(l)} = (w^{(l)})_{k, i, j} \quad \text{for all } l = 0, \ldots, L-1,$$

$$(w^*)_{1,1,k}^{(L)} = (w^{(L)})_{1,1,k} \quad \text{for all } k = 1, \ldots, \tilde{K}_n,$$

$$(w^*)_{1,1,k}^{(L)} = 0 \quad \text{for all } k \notin \{j_1, \ldots, j_{\tilde{K}_n}\}$$

and $(w^*)^{(0)}$ by

$$(w^*)_{k, i, j}^{(0)}(l) = (w_{k, i, j}^{(0)})^{(l)} \quad \text{for all } l = 0, \ldots, L-1,$$

$$(w^*)_{1,1,k}^{(0)}(L) = (w_{1,1,k}^{(0)})^{(L)} \quad \text{for all } k = 1, \ldots, \tilde{K}_n.$$
\[(w^* (0))^{(L)}_{1,1,k} = 0 \quad \text{for all } k \notin \{j_1, \ldots, j_K\}.\]

In the following we set
\[m_{\beta_n}(x) = E(T_{\beta_n} Y | X = x).\]

Furthermore, we assume w.l.o.g. that \(n\) is sufficiently large and that \(\|m\|_\infty \leq \beta_n\) holds.

In the \textit{first step of the proof} we decompose the \(L_2\) error of \(m_n\) in a sum of several terms. We have
\[
\int |m_n(x) - m(x)|^2 P_X(dx) = (E \{ |m_n(X) - Y|^2 | D_n \} - E \{ |m(X) - Y|^2 \}) \cdot 1_{A_n} + \int |m_n(x) - m(x)|^2 P_X(dx) \cdot 1_{A_n^c} + \left[ E \{ |m_n(X) - T_{\beta_n} Y|^2 | D_n \} - E \{ |m_{\beta_n}(X) - T_{\beta_n} Y|^2 \} \right] \cdot 1_{A_n} + \left[ E \{ |m_n(X) - T_{\beta_n} Y|^2 | D_n \} - E \{ |m_{\beta_n}(X) - T_{\beta_n} Y|^2 \} \right] \cdot 1_{A_n} + \left[ 2 \cdot \frac{1}{n} \sum_{i=1}^{n} |m_n(X_i) - T_{\beta_n} Y_i|^2 - 2 \cdot \frac{1}{n} \sum_{i=1}^{n} |m_{\beta_n}(X_i) - T_{\beta_n} Y_i|^2 \right] \cdot 1_{A_n} + \left[ 2 \cdot \frac{1}{n} \sum_{i=1}^{n} |m_n(X_i) - Y_i|^2 - 2 \cdot \frac{1}{n} \sum_{i=1}^{n} |m(X_i) - Y_i|^2 \right] \cdot 1_{A_n} + \int |m_n(x) - m(x)|^2 P_X(dx) \cdot 1_{A_n^c} =: \sum_{j=1}^{5} T_{j,n}.
\]

In the \textit{second step of the proof} we show
\[ET_{1,n} \leq c_{66} \cdot \frac{\log n}{n} \quad \text{and} \quad ET_{3,n} \leq c_{67} \cdot \frac{\log n}{n}.\]

This follows as in the proof of Lemma 1 in Bauer and Kohler (2019).

In the \textit{third step of the proof} we show
\[ET_{5,n} \leq c_{68} \cdot \frac{(\log n)^2}{n}.\]
Due to the definition of $m_n$ and the assumption that $\|m\|_\infty \leq \beta_n$, it holds

$$\int |m_n(x) - m(x)|^2 P_X(dx) \leq 4 \cdot c_1^2 \cdot (\log n)^2.$$ 

Thus it suffices to show

$$P(A_{n}^c) \leq \frac{c_{69}}{n}.$$ 

To do this, we first bound the probability that the weights in the first of the $K_n$ fully connected neural networks differ by at most $\log n$ from $(w^{(l)}_{1,i,j})_{i,j,l \leq L}$ in all components. For large $n$, this probability is bounded from below by

$$\left(\frac{\log n}{40d \cdot (\log n)^2}\right)^{r(r+1)(L-2)} \cdot \left(\frac{\log n}{16d \cdot (\log n)^2 \cdot n^r}\right)^{r(d+1)} \geq n^{-r(d+1)\tau - 0.5}.$$ 

Then the probability that none of the first $n^{-r(d+1)\tau + 1}$ neural networks satisfies this condition is bounded above by

$$(1 - n^{-r(d+1)\tau - 0.5})^{n^{-r(d+1)\tau + 1}} \leq \exp \left(-n^{-r(d+1)\tau - 0.5}\right) \leq \exp(-n^{0.5}).$$ 

Assumption (49) implies $K_n \geq n^{-r(d+1)\tau + 1} \cdot \tilde{K}_n$ for large $n$. Thus we can apply this construction successively for all $\tilde{K}_n$ weights $(w^{(l)}_{k,i,j})_{i,j,l \leq L}$. The probability that there exists $k \in \{1, \ldots, \tilde{K}_n\}$ such that none of the $\tilde{K}_n$ weight vectors of the fully connected neural network differs from $(w^{(l)}_{k,i,j})_{i,j,l \leq L}$ by at most $\log n$ is then for large $n$ bounded from above by

$$\tilde{K}_n \cdot \exp(-n^{0.5}) \leq n^n \cdot \exp(-n^{0.5}) \leq \frac{c_{70}}{n}. $$

Hence, for large $n$ it is

$$P(A_{n}^c) \leq \frac{c_{70}}{n} + P\left\{ \max_{i=1,\ldots,n} |Y_i| > \sqrt{\beta_n} \right\} \leq \frac{c_{70}}{n} + n \cdot P\{|Y| > \sqrt{\beta_n}\} \leq \frac{c_{71}}{n},$$

where the last inequality holds because of (45) and (51).

In the fourth step of the proof we show that the assumptions (12) - (14) of Lemma 1 are satisfied which means that

$$\| (\nabla_w F)(w) \| \leq L_n$$

for all $w \in S := \{v : \|v - w^{(0)}\| \leq 2 \cdot \sqrt{F(w^{(0)})} + 1\}$,

$$\| (\nabla_w F)(w) - (\nabla_w F)(\bar{w}) \| \leq L_n \cdot \|w - \bar{w}\|.$$
for all \( w, \bar{w} \in S \) and
\[
|F(w^*) - F((w^*)^{(0)})| \\
\leq D_n \cdot \|(w^*)^{(L)}_{i,j,k}\|_{k=1,\ldots,K_n} \cdot \|(w^{(0)}_{i,j,k})_{i,j,k,lL<L} - ((w^{(0)})^{(l)}_{i,j,k})_{i,j,k,lL<L}\|
\]
for all
\[
(w^{(l)}_{i,j,k})_{i,j,k,lL<L} \in \tilde{S} \\
:= \left\{ (\bar{w}^{(l)}_{i,j,k})_{i,j,k,lL<L} : \|(\bar{w}^{(l)}_{i,j,k})_{i,j,k,lL<L} - ((w^{(0)})^{(l)}_{i,j,k})_{i,j,k,lL<L}\| \leq \sqrt{2 \cdot F(w^{(0)})} \right\}
\]
hold, if \( A_n \) holds.
If \( A_n \) holds, then we have
\[
F_n(w^{(0)}) = \frac{1}{n} \sum_{i=1}^{n} y_i^2 \leq \beta_n.
\]
Let \( w \in S \). Then we have
\[
\|(w^{(l)}_{i,j,k})_{i,j,k,lL<L}\|_\infty \leq \|w - w^{(0)}\| + \|(w^{(0)}_{i,j,k})_{i,j,k,lL<L}\|_\infty \\
\leq 2 \cdot \sqrt{F_n(w^{(0)})} + 1 + c_{72} \cdot (\log n)^2 \\
\leq c_{73} \cdot (\log n)^2
\]
and
\[
\|(w^{(L)}_{i,j,k})_{i,j,k,lL=L}\|_\infty \leq \|w - w^{(0)}\| + \|(w^{(0)}_{i,j,k})_{i,j,k,lL=L}\|_\infty \\
\leq 2 \cdot \sqrt{F_n(w^{(0)})} + 1 \\
\leq c_{74} \cdot (\log n)^{3/2}.
\]
Hence (18)-(23) are satisfied for \( B_n = c_{73} \cdot (\log n)^2 \) and \( \gamma_n^* = c_{74} \cdot (\log n)^{3/2} \). By Lemma 2 and Lemma 3 we get that (12) and (13) are satisfied provided that \( L_n \geq K_n^{3/2} \cdot (\log n)^{6L+2} \).

Furthermore, let \( \tilde{w} \) such that \( (\tilde{w}^{(l)}_{i,j,k})_{i,j,k,lL<L} \in \tilde{S} \). Then we obtain as in the proof of Theorem 1
\[
|F_n(w^*) - F_n((w^*)^{(0)})| \\
\leq \left( \frac{2}{n} \sum_{i=1}^{n} \left( f_{w^*}(X_i) + f_{(w^*)^{(0)}}(X_i) \right)^2 + \frac{8}{n} \sum_{i=1}^{n} y_i^2 \right)^{1/2} \\
\cdot \left( \frac{1}{n} \sum_{i=1}^{n} \left( \sum_{k=1}^{K_n} |(w^*)_{i,j,k}|^2 \cdot \sum_{k=1}^{K_n} \left| f_{w^*,k,1}^{(L)}(X_i) - f_{(w^*)^{(0)},k,1}(X_i) \right|^2 \right) \right)^{1/2}. 
\]

35
With
\[
\left( \frac{1}{n} \sum_{i=1}^{n} \left( \sum_{k=1}^{K_n} (w_i^*)_{1,1,k}^2 \cdot \sum_{k=1}^{K_n} \left| f_{w_i^*,k,1}^{(L)}(X_i) - f_{(w_i^*)_{(0)},k,1}^{(L)}(X_i) \right|^2 \right) \right)^{1/2}
\]
\[
\leq \left\| (w_i^*)_{1,1,k}^{(L)} \right\|_{k=1,...,K_n} || c_{75} \cdot (\log n)^{2L} \cdot \left( \left( \tilde{w}_{i,j,k}^{(l)} \right)_{i,j,k,l;L} - \left( (w_i^*)_{(0)}^{(l)} \right)_{i,j,k,l;L} \right) \right\|
\]
and since \( \tilde{w}_{i,j,k}^{(l)} \) for \( i,j,k,l;L \in \tilde{S} \) we get
\[
\left( \frac{2}{n} \sum_{i=1}^{n} \left( f_{w^*}(X_i) + f_{(w^*)_{(0)}}(X_i) \right)^2 + \frac{8}{n} \sum_{i=1}^{n} Y_i^2 \right)^{1/2}
\]
\[
\leq \left( 4 \cdot \sum_{k=1}^{K_n} \left( w_i^* \right)_{1,1,k}^{(L)} \cdot \max_{i=1,...,n} \sum_{k=1}^{K_n} \left| f_{w_i^*,k,1}^{(L)}(X_i) - f_{(w_i^*)_{(0)},k,1}^{(L)}(X_i) \right|^2 \right)^{1/2}
\]
\[
+ 16 \cdot \frac{1}{n} \sum_{i=1}^{n} f_{(w^*)_{(0)}}(X_i)^2 + \frac{8}{n} \sum_{i=1}^{n} Y_i^2 \right)^{1/2}
\]
\[
\leq \left( c_{77} \cdot M_n^2 \cdot (\log n)^{4L+1} + 16 \cdot \beta_n^2 + 8 \cdot \beta_n \right)^{1/2}
\]
\[
\leq c_{78} \cdot M_n \cdot (\log n)^{2L+1}.
\]
Summarizing these steps yields
\[
| F_n(w^*) - F_n((w^*)_{(0)}) |
\]
\[
\leq c_{79} \cdot (\log n)^{4L+1} \cdot M_n \cdot || (w_i^*)_{1,1,k}^{(L)} ||_{k=1,...,K_n} \cdot || (\tilde{w}_{i,j,k}^{(l)})_{i,j,k,l;L} - ((w_i^*)_{(0)})_{i,j,k,l;L} \right||
\]
Thus \([14]\) is satisfied with
\[
D_n = c_{79} \cdot M_n \cdot (\log n)^{4L+1}.
\]
Let \( \epsilon > 0 \) be arbitrary. In the fifth step of the proof we show
\[
ET_{2,n} \leq c_{80} \cdot \frac{n^{r-d+\epsilon}}{n}.
\]
Let \( W_n \) be the set of all weight vectors \( (w_i^{(l)})_{i,j,k,l} \) which satisfy
\[
| w_i^{(l)}_{1,1,k} | \leq c_{81} \cdot (\log n)^2 \quad (k = 1, \ldots, K_n),
\]
\[ |w_{i,j,k}^{(l)}| \leq (20d+1) \cdot (\log n)^2 \quad (l = 1, \ldots, L-1) \]

and

\[ |w_{i,j,k}^{(0)}| \leq (8d+1) \cdot (\log n)^2 \cdot n^z. \]

From Lemma 1 we know for \( n \) large that

\[ \|((w(t^{(n)}))^{(L)}_{1,1,1})_{k=1,\ldots,K_n} - ((w^{(0)})^{(L)}_{1,1,1})_{k=1,\ldots,K_n}\| \leq \sqrt{2F_n(w^{(0)})} \leq (\log n)^2 \]

and

\[ \|((w(t^{(n)}))^{(l)}_{i,j,k,l:L})_{i,j,k:l:L} - ((w^{(0)})^{(l)}_{i,j,k,l:L})_{i,j,k:l:L}\| \leq \sqrt{2F_n(w^{(0)})} \leq (\log n)^2. \]

This and the initial choice of \( w^{(0)} \) imply that we have on \( A_n \) for \( n \) large

\[ w^{(t)} \in W_n \quad (t = 0, \ldots, t_n). \]

Thus, for any \( u > 0 \) we get

\[
P\{T_{2,n} > u\} \leq P \left\{ \exists f \in F_n : E \left( \frac{f(X)}{\beta_n} - T_{\beta_n} Y \right)^2 \right. - E \left( \frac{m_{\beta_n}(X)}{\beta_n} - T_{\beta_n} Y \right)^2 \\
- \left. \frac{1}{n} \sum_{i=1}^{n} \left( \left| \frac{f(X_i)}{\beta_n} - T_{\beta_n} Y_i \right|^2 - \left| \frac{m_{\beta_n}(X_i)}{\beta_n} - T_{\beta_n} Y_i \right|^2 \right) \right\} \leq \frac{1}{2} \cdot \left( \frac{u}{\beta_n^2} + \frac{1}{n} \sum_{i=1}^{n} \left( \left| \frac{f(X_i)}{\beta_n} - T_{\beta_n} Y_i \right|^2 - \left| \frac{m_{\beta_n}(X_i)}{\beta_n} - T_{\beta_n} Y_i \right|^2 \right) \right),
\]

where

\[ F_n = \{ T_{\beta_n} f_w : w \in W_n \}. \]

Application of Lemma 4 yields for \( x_1^n \in \text{supp}(X) \) and \( \alpha = c_{82} \)

\[ N_1 \left( \delta, \left\{ \frac{1}{\beta_n} \cdot f : f \in F_n \right\}, x_1^n \right) \leq N_1 \left( \delta \cdot \beta_n, F_n, x_1^n \right) \leq \left( c_{83} \cdot \beta_n \right)^{c_{84} (\log n)^{2d} \cdot n^r \cdot d \cdot (\log n)^2 \cdot (L-1) \cdot d} \cdot \frac{K_n \cdot (\log n)^2}{\beta_n^2} \cdot \frac{d}{k} + c_{85}.
\]

For \( \delta > 1/n \) and \( k \) large enough, we obtain

\[ N_1 \left( \delta, \left\{ \frac{1}{\beta_n} \cdot f : f \in F_n \right\}, x_1^n \right) \leq c_{86} \cdot n^{c_{87} \cdot n^r \cdot d + 1/2}.
\]

This together with Theorem 11.4 in Györfi et al. [2002] leads for \( u \geq 1/n \) to

\[
P\{T_{2,n} > u\} \leq 14 \cdot c_{86} \cdot n^{c_{87} \cdot n^r \cdot d + 1/2} \cdot \exp \left( - \frac{n}{5136 \cdot \beta_n^2} \cdot u \right).
\]
For $\epsilon_n \geq 1/n$ we can conclude
\[
\mathbb{E}\{T_{2,n}\} \leq \epsilon_n + \int_{\epsilon_n}^{\infty} \mathbb{P}\{T_{2,n} > u\} \, du \\
\leq \epsilon_n + 14 \cdot c_{86} \cdot n^{c_{87} \cdot n^{\tau-d+\epsilon/2}} \cdot \exp\left(\frac{n}{5136 \cdot \beta_n^2 \cdot \epsilon_n}\right) \cdot \frac{5136 \cdot \beta_n^2}{n}.
\]
Setting
\[
\epsilon_n = \frac{5136 \cdot \beta_n^2}{n} \cdot c_{87} \cdot n^{\tau-d+\epsilon/2} \cdot \log n
\]
yields the assertion of the fifth step of the proof.

In the sixth step of the proof we show
\[
\mathbb{E}\{T_{4,n}\}
\]
\[
\leq c_{88} \cdot \left( \sup_{(\bar{\omega}^{(l)})_{i,j,k}, (\omega^{(l)})_{i,j,k}} \int |\sum_{k=1}^{K_n} w^{(L)}_{1,1,k} \cdot f^{(L)}_{W,k,1}(x) - m(x)|^2 \mathbb{P}(dx) \right)
\]
\[
+ c_{89} \cdot \log n \cdot c_{90} \cdot n^{\tau-d+\epsilon} \cdot \log n + c_{91} \cdot M_n^2 \cdot (\log n)^{4L+3/2}.
\]
Since
\[
|T_{\beta_n} z - y| \leq |z - y| \quad \text{for } |y| \leq \beta_n
\]
we obtain
\[
T_{4,n}/2
\]
\[
= \left[ \frac{1}{n} \sum_{i=1}^{n} |m_n(X_i) - Y_i|^2 - \frac{1}{n} \sum_{i=1}^{n} |m(X_i) - Y_i|^2 \right] \cdot 1_{A_n}
\]
\[
\leq \left[ \frac{1}{n} \sum_{i=1}^{n} \left| f_{w^{(t_n)}}(X_i) - Y_i \right|^2 - \frac{1}{n} \sum_{i=1}^{n} |m(X_i) - Y_i|^2 \right] \cdot 1_{A_n}
\]
\[
= \left[ F_n(w^{(t_n)}) - \frac{1}{n} \sum_{i=1}^{n} |m(X_i) - Y_i|^2 \right] \cdot 1_{A_n}.
\]
The application of Lemma 1 implies
\[
\mathbb{E}\{T_{4,n}/2\}
\]
\[
\leq \mathbb{E}\left\{ \left[ F_n\left((w^*)^{(0)}\right) + D_n \cdot \|((w^*)^{(L)})_{1,1,k} = 1, \ldots, K_n\| \cdot \sqrt{2 \cdot F_n\left(w^{(0)}\right)} \right. \right.
\]
\[
\left. + \left\|\left((w^*)^{(L)}\right)_{1,1,k} = 1, \ldots, K_n - ((w^*)^{(0)})^{(L)}_{1,1,k} = 1, \ldots, K_n\right\|^2 \right] \cdot 1_{A_n} \right\}.
\]
38
Summarizing the above results we get the assertion.

Due to step 4 we have

\[ D_n = c_{79} \cdot M_n \cdot (\log n)^{4L+1}. \]

Using the same arguments as in step 2 and 5 of the proof we obtain

\[
\begin{align*}
&\mathbb{E}\left\{ \left( F_n\left( (w^*)^{(0)} \right) - \frac{1}{n} \sum_{i=1}^{n} |m(X_i) - Y_i|^2 \right) 
\right. \\
&\quad + c_{92} \cdot M_n \cdot (\log n)^{4L+1} \cdot \|((w^*)^{(L)}_{1,1,k})_{k=1,...,K_n}\| : \sqrt{2 \cdot F_n\left( (w^*)^{(0)} \right)} \\
&\quad + \frac{\|((w^*)^{(L)}_{1,1,k})_{k=1,...,K_n} - \left( (w^*)^{(0)}\right)^{(L)}_{1,1,k}\|_2^2}{2} + \frac{F_n\left( (w^*)^{(0)} \right)}{t_n} \\
- &\left. 2 \cdot \left( \mathbb{E}\left\{ \left| \sum_{k=1}^{K_n} (w^*)^{(L)}_{1,1,k} \cdot f^{(L)}_{w^*,j,1}(X) - Y \right|^2 | \mathcal{D}_n, w^*(0) \right\} - \mathbb{E}\{ |m(X) - Y|^2 \} \right) \right\} \right) \right) 1_{A_n} \right) \right).
\end{align*}
\]

This implies

\[
\begin{align*}
&\mathbb{E}\{ T_{i,n/2} \} \\
\leq 2 \cdot \left( \sup_{u^{(l)}_{i,j,k} \leq u^{(l)}_{i,j,k}; l \leq \log n (i=0,...,L-1)} \int \left| \sum_{k=1}^{K_n} w_{1,1,k}^{(L)} \cdot f^{(L)}_{w^*,j,1}(x) - m(x) \right|^2 P_X(dx) \right) \\
&\quad + c_{91} \cdot \frac{\log n}{n} + c_{92} \cdot \frac{n^{r-d+\epsilon}}{n} + c_{95} \cdot M_n^2 \cdot (\log n)^{4L+3/2}.
\end{align*}
\]

Summarizing the above results we get the assertion.
To prove Theorem 2, we use the following lemma, which provides another bound on the approximation error. Furthermore, it ensures that the outer weights are sufficiently small.

**Lemma 6.** Let \( 1/2 \leq p \leq 1, C > 0, \) let \( f : \mathbb{R}^d \to \mathbb{R} \) be a \((p, C)\)-smooth function and let \( X \) be a \( \mathbb{R}^d \)-valued random variable with \( \text{supp}(X) \subseteq [0, 1]^d \). Let \( l \in \mathbb{N}, 0 < \delta < 1/2 \) with

\[
c_{96} \cdot \delta = \frac{1}{2^l} \leq c_{97} \cdot \delta
\]

and let \( L, r, s \in \mathbb{N} \) with \( L \geq 2 \) and \( r \geq 2d \). Furthermore, let

\[
\tilde{K}_n \geq \left( l \cdot (2^l + 1)^{2d} + 1 \right)^3.
\]

Then there exist

\[
w^{(l)}_{k,i,j} \in [-20d \cdot (\log n)^2, 20d \cdot (\log n)^2] \quad \text{for } l = 1, \ldots, L, k = 1, \ldots, \tilde{K}_n
\]

and

\[
w^{(0)}_{k,i,j} \in \left[ -\frac{8 \cdot d \cdot (\log n)^2}{\delta}, \frac{8 \cdot d \cdot (\log n)^2}{\delta} \right] \quad \text{for } k = 1, \ldots, \tilde{K}_n
\]

such that for all \( \bar{w} \) satisfying \( |w^{(l)}_{i,j,k} - w^{(l)}_{i,j,k}| \leq \log n \) (\( l = 0, \ldots, L - 1 \)) we have for \( n \) sufficiently large

\[
\int \left| \sum_{k=1}^{\tilde{K}_n} w^{(L)}_{1,1,k} \cdot f^{(L)}_{\bar{w},k,1}(x) - f(x) \right|^2 P_X(dx) \leq c_{98} \cdot \left( l^2 \cdot \delta + \delta^{2p} + \frac{l \cdot (2^l + 1)^{2d}}{n^s} \right),
\]

\[
\left| \sum_{k=1}^{\tilde{K}_n} w^{(L)}_{1,1,k} \cdot f^{(L)}_{\bar{w},k,1}(x) \right| \leq c_{99} \cdot \left( 1 + \frac{(2^l + 1)^{2d}}{n^s} \right) \quad (x \in [0, 1]^d)
\]

and

\[
\sum_{k=1}^{\tilde{K}_n} |w^{(L)}_{1,1,k}|^2 \leq \frac{c_{100}}{2^2 \cdot 2^d}.
\]

*Proof.* The proof follows from the proof of Lemma 7 in Kohler and Krzyżak (2022a). \( \square \)

### 4.4. Proof of Theorem 2

Let \( l = \lfloor 1/1+d \log_2 n \rfloor \). Then condition \( (53) \) holds for \( \delta = n^{-1/(1+d)} \). Set

\[
\tilde{K}_n = (l \cdot (2^l + 1)^{2d} + 1)^3 \approx c_{101} \cdot (\log n)^3 \cdot n^{\frac{6d}{1+d}}, \quad N_n = n^{c_{102}}
\]
and define the weight vector $w$ as in Lemma 6. Then we obtain by Lemma 6 that assumption (46) is satisfied for $M_n = \frac{c_{103}}{n^{d+1}}$. Assumption (47) follows directly from (55) of Lemma 6 for $s$ sufficiently large.

By Theorem 4, $\tau = \frac{1}{1+d}$ and Lemma 6 where $s$ is sufficiently large we get for large $n$

$$
\mathbb{E} \int |m_n(x) - m(x)|^2 P_X(dx) \leq c_{104} \cdot \left( \frac{n^{\frac{1}{1+d}}}{n^{d+\epsilon}} + \frac{c_{105}}{n^{d+1}} \right) + \sup_{|\omega|_{i,j,k} \leq \log n} \left( \left\| w_{1,1,k}^{(l)} \cdot f_{w,1,1}^{(l)}(x) - m(x) \right\|_{2}^2 P_X(dx) \right)
$$

$$
\leq c_{106} \cdot \left( \frac{n^{\frac{1}{1+d}}}{n^{d+\epsilon}} + \frac{(\log n)^{4L+3/2}}{n^{d+1}} + \frac{1}{n^{d+1}} + \frac{\log n \cdot n^{\frac{2d}{1+d}}}{n^{s}} \right)
$$

for $s$ sufficiently large. □

### 4.5. Auxiliary results for the proof of Theorem 3

In order to prove Theorem 3, we use the following lemma, which controls the complexity of a set of over-parametrized deep neural networks for interaction models.

**Lemma 7.** Let $\alpha \geq 1$, $\beta > 0$ and let $A, B, C \geq 1$. Let $\sigma : \mathbb{R} \to \mathbb{R}$ be $k$-times differentiable such that all derivatives up to order $k$ are bounded on $\mathbb{R}$. Let $\mathcal{F}$ be the set of all functions

$$
f_w(x) = \sum_{I \subseteq \{1, \ldots, d\} : |I| = d^*} f_{w,I}(x_I)
$$

where $f_{w,I}$ is defined by (1)–(3) with $d$ replaced by $d^*$ and weight vector $w_I$, $w = (w_I)_{I \subseteq \{1, \ldots, d\} : |I| = d^*}$, and where for any $I \subseteq \{1, \ldots, d\}$ with $|I| = d^*$ the weight vector $w_I$ satisfies

$$
\sum_{j=1}^{K_n} |(w_I)^{(L)}_{1,1,j}| \leq C, \quad (57)
$$

$$
|w_I^{(l)}_{i,j,k}| \leq B \quad (k \in \{1, \ldots, K_n\}, i, j \in \{1, \ldots, r\}, l \in \{1, \ldots, L - 1\}) \quad (58)
$$

and

$$
|w_I^{(0)}_{k,i,j}| \leq A \quad (k \in \{1, \ldots, K_n\}, i \in \{1, \ldots, r\}, j \in \{1, \ldots, d\}). \quad (59)
$$

Then we have for any $1 \leq p < \infty$, $0 < \epsilon < \beta$ and $x^n \in [-\alpha, \alpha]^d$

$$
\mathcal{N}_p(\epsilon, \{T_{\beta f} : f \in \mathcal{F}\}, x^n)
$$

41
Proof. See Lemma 8 in Kohler and Krzyżak (2022a). □

4.6. Proof of Theorem 3

Let \( l = \lfloor \frac{1}{1+d^*} \log_2 n \rfloor \) and \( N_n = n^{c_{111}}. \) Furthermore, let

\[
\tilde{K}_n = \left( \frac{d}{d^*} \right) (l \cdot (2^l + 1) 2^{d^*} + 1)^3 \approx c_{112} \cdot (\log n)^3 \cdot n^{\frac{d^*}{1+d^*}}.
\]

Then (53) holds for \( \delta = n^{-1/(1+d^*)}. \) Define the weight vector \( w \) such that the components are chosen according to Lemma 6 so that they approximate \( m_I. \)

Assumption (46) and (47) of Theorem 4 are satisfied for \( w \) since

\[
X_I \subseteq \{1, \ldots, d^*\}: |I| = d^* \sum_{k=1}^{\tilde{K}_n} |(w_I)^{(L)}_{1,1,k}|^2 \leq c_{113} \cdot n^{-\frac{2d^*}{1+d^*}}
\]

and

\[
\sum_{I \subseteq \{1, \ldots, d^*\}: |I| = d^*} \sum_{k=1}^{\tilde{K}_n} \left| (w_I)^{(L)}_{1,1,k} \cdot f^{(L)}(w_I)_{k,1}(x) \right| \leq c_{114} \cdot \left( 1 + \frac{n^{2d^*/(1+d^*)}}{n^s} \right)
\]

hold.

Then we obtain by application of Lemma 7 the assertion of Theorem 4 for interaction models. Therefore the proof of Theorem 3 follows similarly to the proof of Theorem 2. By applying the assertions of Theorem 4 and Lemma 6 we get for \( \tau = \frac{1}{1+d^*} \) and \( s \) sufficiently large

\[
E \int |m_n(x) - m(x)|^2 P_X(dx) \leq c_{115} \cdot \left( \frac{n^{1+d^*+\epsilon}}{n} + c_{113} \cdot n^{-\frac{2d^*}{1+d^*}} \cdot (\log n)^4 L + \frac{1}{2} \cdot \sup_{t=0, \ldots, L-1} \left( c_{116} \cdot \left( \frac{n^{1+d^*+\epsilon}}{n} + \frac{(\log n)^4 L + \frac{1}{2} \cdot (\log n)^2}{n^{1+d^*}} + \frac{1}{2} \cdot \log n \cdot \frac{n^{2d^*}}{n^s} \right) \right) \right)
\]

\[
\leq c_{117} \cdot n^{-\frac{1}{1+d^*} + \epsilon}.
\]
References

A. Proof of Lemma 2

Proof. We have

\[ \| \nabla_w F_n(w) \|^2 = \sum_{k,i,j,l} \left( \frac{2}{n} \sum_{s=1}^{n} \left( Y_s - f_w(X_s) \right) \cdot \frac{\partial f_w}{\partial w_{k,i,j}^{(l)}}(X_s) \right)^2 \]

\[ \leq 4 \cdot \sum_{k,i,j,l} \frac{1}{n} \sum_{s=1}^{n} \left( Y_s - f_w(X_s) \right)^2 \cdot \left( \frac{\partial f_w}{\partial w_{k,i,j}^{(l)}}(X_s) \right)^2 \]

\[ \leq c_{118} \cdot K_n \cdot L \cdot r^2 \cdot d \cdot \max_{k,i,j,l,s} \left( \frac{\partial f_w}{\partial w_{k,i,j}^{(l)}}(X_s) \right)^2 \cdot \frac{1}{n} \sum_{s=1}^{n} \left( Y_s - f_w(X_s) \right)^2. \]
The partial derivative of \( f \) is given by

\[
\frac{\partial f_w}{\partial w_{k,i,j}^{(l)}}(x) = \sum_{s_{i+2} = 1}^{r} \cdots \sum_{s_{L-1} = 1}^{r} f_{k,j}^{(l)}(x) \cdot \sigma' \left( \sum_{t=1}^{r} w_{k,i,l,t}^{(l)} \cdot f_{k,t}^{(l)}(x) + w_{k,i,l,0}^{(l)} \right) \cdot w_{k,s_{i+2},i,j}^{(l)} \cdot \sigma' \left( \sum_{t=1}^{r} w_{k,s_{i+2},i,j,t}^{(l)} \cdot f_{k,t}^{(l)}(x) + w_{k,s_{i+2},i,j,0}^{(l+1)} \right) \cdot w_{k,s_{i+3},i,j}^{(l+2)} \\
\cdot \sigma' \left( \sum_{t=1}^{r} w_{k,s_{i+3},i,j,t}^{(L-2)} \cdot f_{k,t}^{(L-2)}(x) + w_{k,s_{i+3},i,j,0}^{(L-2)} \right) \cdot w_{k,1,s_{i+1}}^{(L-1)} \\
\cdot \sigma' \left( \sum_{t=1}^{r} w_{k,1,s_{i+1},t}^{(L-1)} \cdot f_{k,t}^{(L-1)}(x) + w_{k,1,s_{i+1},0}^{(L-1)} \right) \cdot w_{1,1,k}^{(L)} - (60)
\]

where we have used the abbreviations

\[
f_{k,j}^{(0)}(x) = \begin{cases} x(j) & \text{if } j \in \{1, \ldots, d\} \\ 1 & \text{if } j = 0 \end{cases}
\]

and

\[
f_{k,0}^{(l)}(x) = 1 \quad (l = 1, \ldots, L - 1).
\]

Together with (18) and (19) we obtain

\[
\max_{k,i,j,l,s} \left( \frac{\partial f_w}{\partial w_{k,i,j}^{(l)}}(X_s) \right)^2 \leq c_{19} \cdot r^{2L} \cdot \max\{\|\sigma\|_{\infty}^{2L}, 1\} \cdot B_n^{2L} \cdot \gamma_n^2 \cdot \alpha_n^2.
\]

In the next step of the proof we want to show, that

\[
|f_w(x) - f_v(x)| \leq 2 \cdot K_n \cdot \max\{\|\sigma\|_{\infty}^{L}, 1\} \cdot \gamma_n^L \cdot (2r + 1)^L \cdot B_n^L \cdot \alpha_n \cdot \|w - v\|_{\infty} \cdot \max\{\|\sigma\|_{\infty}, 1\}.
\]

Let \( \tilde{f}_{k,i}^{(l)} \) be defined by

\[
\tilde{f}_{k,i}^{(l)}(x) = \sigma \left( \sum_{j=1}^{r} v_{k,i,j}^{(l-1)} \cdot \tilde{f}_{k,j}^{(l-1)}(x) + v_{k,i,0}^{(l-1)} \right)
\]

for \( l = 2, \ldots, L \) and

\[
\tilde{f}_{k,i}^{(1)}(x) = \sigma \left( \sum_{j=1}^{d} v_{k,i,j}^{(0)} \cdot x(j) + v_{k,i,0}^{(0)} \right).
\]

First, we show by induction that

\[
|f_{i,j}^{(l)}(x) - \tilde{f}_{i,j}^{(l)}(x)| \leq \max\{\|\sigma\|_{\infty}^{l}, 1\} \cdot (2r + 1)^l \cdot B_n^l \cdot \alpha_n
\]

46
\begin{align*}
\cdot \max_{i,j,s:s<L} |w_{k,i,j}^{(s)} - v_{k,i,j}^{(s)}| \cdot \max\{\|\sigma\|_\infty, 1\} 
\end{align*}

holds for \( l = 1, \ldots, L \) and \( x \in [-\alpha_n, \alpha_n]^d \).

The function \( \sigma \) is differentiable and its derivative is bounded, hence \( \sigma \) is Lipschitz continuous with Lipschitz constant \( \|\sigma'\|_\infty \). This implies

\[
|f^{(1)}_{k,j}(x) - \bar{f}^{(1)}_{k,j}(x)| \leq \|\sigma'\|_\infty \cdot \left( \sum_{j=1}^{d} |w_{k,i,j}^{(0)} - v_{k,i,j}^{(0)}| \cdot |x^{(j)}| + |w_{k,i,0}^{(0)} - v_{k,i,0}^{(0)}| \right)
\leq \|\sigma'\|_\infty \cdot (2r + 1) \cdot \alpha_n \cdot \max_{i,j,s:s<L} |w_{k,i,j}^{(s)} - v_{k,i,j}^{(s)}|.
\]

Assume (61) holds for some \( l - 1 \) with \( l = 2, \ldots, L - 1 \). Then we have

\[
\left| f^{(l)}_{k,j}(x) - \bar{f}^{(l)}_{k,j}(x) \right|
\leq \|\sigma'\|_\infty \cdot \left( \sum_{j=1}^{r} |w_{k,i,j}^{(l-1)}| \cdot |f^{(l-1)}_{k,j}(x) - \bar{f}^{(l-1)}_{k,j}(x)| \right)
\leq \|\sigma'\|_\infty \cdot \left( r \cdot B_n \cdot \max_{j=1,\ldots,r} \left| \right. \right.
\leq \max\{\|\sigma'\|_\infty, 1\} \cdot \max_{i,j,s:s<L} |w_{k,i,j}^{(s)} - v_{k,i,j}^{(s)}| \cdot \max\{\|\sigma\|_\infty, 1\}
\leq \max\{\|\sigma'\|_\infty^l, 1\} \cdot (2r + 1)^l \cdot B_n^L \cdot \alpha_n \cdot \max_{i,j,s:s<L} |w_{k,i,j}^{(s)} - v_{k,i,j}^{(s)}| \cdot \max\{\|\sigma\|_\infty, 1\}.
\]

This implies

\[
|f_w(x) - f_\nu(x)|
= \left| \sum_{j=1}^{K_n} w_{1,1,j}^{(L)} \cdot f_{j,1}^{(L)}(x) - \sum_{j=1}^{K_n} v_{1,1,j}^{(L)} \cdot \bar{f}_{j,1}^{(L)}(x) \right|
\leq \left| \sum_{j=1}^{K_n} w_{1,1,j}^{(L)} \left( f_{j,1}^{(L)}(x) - \bar{f}_{j,1}^{(L)}(x) \right) \right| + \left| \sum_{j=1}^{K_n} \left( w_{1,1,j}^{(L)} - v_{1,1,j}^{(L)} \right) \cdot \bar{f}_{j,1}^{(L)}(x) \right|
\leq K_n \cdot \max_j \left| w_{1,1,j}^{(L)} \right| \cdot \max_j \left| f_{j,1}^{(L)}(x) - \bar{f}_{j,1}^{(L)}(x) \right|
+ \left| K_n \cdot \max_j \left( w_{1,1,j}^{(L)} - v_{1,1,j}^{(L)} \right) \cdot \max\{\|\sigma\|_\infty, 1\} \right|
\leq 2 \cdot K_n \cdot \gamma_n \cdot \max\{\|\sigma'\|_\infty, 1\} \cdot (2r + 1)^L \cdot B_n^L \cdot \alpha_n \cdot \|w - \nu\|_\infty \cdot \max\{\|\sigma\|_\infty, 1\}.
\]

47
Together with assumption (20) we can conclude
\[
\frac{1}{n} \sum_{s=1}^{n} (Y_s - f_w(X_s))^2
\]
\[
\leq 2 \cdot F_n(v) + \frac{2}{n} \sum_{s=1}^{n} (f_v(X_s) - f_w(X_s))^2
\]
\[
\leq 2 \cdot F_n(v) + 8 \cdot K_n^2 \cdot (\gamma_n^*)^2 \cdot \max\{\|\sigma'\|^2_{\infty}, 1\} \cdot (2r + 1)^{2L} \cdot B_n^{2L} \cdot \alpha_n^2
\]
\[
\cdot \max\{\|\sigma\|_{\infty}, 1\}^2 \cdot \frac{8t_n}{L_n} \cdot \max\{F_n(v), 1\}.
\]

By summarizing the above results we obtain the assertion. \qed

B. Proof of Lemma 3

Proof. We have
\[
\|\nabla_w F_n(w_1) - \nabla_w F_n(w_2)\|^2
\]
\[
= \sum_{k,i,j,l} \left( \frac{2}{n} \sum_{s=1}^{n} (Y_s - f_{w_1}(X_s)) \cdot \frac{\partial f_{w_1}}{\partial w_{k,i,j}^{(l)}}(X_s) 
\right.
\]
\[
- \left( \frac{2}{n} \sum_{s=1}^{n} (Y_s - f_{w_2}(X_s)) \cdot \frac{\partial f_{w_2}}{\partial w_{k,i,j}^{(l)}}(X_s) \right)^2
\]
\[
\leq 8 \cdot \sum_{k,i,j,l} \left( \frac{1}{n} \sum_{s=1}^{n} (f_{w_2}(X_s) - f_{w_1}(X_s)) \cdot \frac{\partial f_{w_1}}{\partial w_{k,i,j}^{(l)}}(X_s) \right)^2
\]
\[
+ 8 \cdot \sum_{k,i,j,l} \left( \frac{1}{n} \sum_{s=1}^{n} (Y_s - f_{w_2}(X_s)) \cdot \left( \frac{\partial f_{w_1}}{\partial w_{k,i,j}^{(l)}}(X_s) - \frac{\partial f_{w_2}}{\partial w_{k,i,j}^{(l)}}(X_s) \right) \right)^2
\]
\[
\leq 8 \cdot \sum_{k,i,j,l} \max_{s=1,...,n} \left( \frac{\partial f_{w_1}}{\partial w_{k,i,j}^{(l)}}(X_s) \right)^2 \cdot \frac{1}{n} \sum_{s=1}^{n} (f_{w_2}(X_s) - f_{w_1}(X_s))^2
\]
\[
+ 8 \cdot \frac{1}{n} \sum_{s=1}^{n} (Y_s - f_{w_2}(X_s))^2 \cdot \sum_{k,i,j,l} \max_{s=1,...,n} \left( \frac{\partial f_{w_1}}{\partial w_{k,i,j}^{(l)}}(X_s) - \frac{\partial f_{w_2}}{\partial w_{k,i,j}^{(l)}}(X_s) \right)^2.
\]

From the proof of Lemma 2 we can conclude
\[
\sum_{k,i,j,l} \max_{s=1,...,n} \left( \frac{\partial f_{w_1}}{\partial w_{k,i,j}^{(l)}}(X_s) \right)^2
\]
\[
\leq c_{120} \cdot K_n \cdot L \cdot r^2 \cdot d \cdot r^{2L} \cdot \max\{\|\sigma'\|^2_{\infty}, 1\} \cdot B_n^{2L} \cdot (\gamma_n^*)^2 \cdot \alpha_n^2.
\]
\[
\frac{1}{n} \sum_{s=1}^{n} (f_{w_2}(X_s) - f_{w_1}(X_s))^2 \\
\leq 4 \cdot K_n^2 \cdot (\gamma_n)^2 \cdot \max\{\|\sigma\|_\infty^2, 1\} \cdot (2r + 1)^{2L} \cdot B_{n}^{2L} \cdot \alpha_n^2 \cdot \max\{\|\sigma\|_\infty, 1\}^2 \|w_1 - w_2\|^2,
\]

and

\[
\frac{1}{n} \sum_{s=1}^{n} (Y_s - f_{w_2}(X_s))^2 \\
\leq 2 \cdot F_n(v) + 8 \cdot K_n^2 \cdot (\gamma_n)^2 \cdot \max\{\|\sigma\|_\infty^2, 1\} \cdot (2r + 1)^{2L} \cdot B_{n}^{2L} \cdot \alpha_n^2 \cdot \max\{\|\sigma\|_\infty, 1\}^2 \frac{8t_n}{L_n} \cdot \max\{F_n(v), 1\}.
\]

So it remains to bound

\[
\sum_{k, i, j, l} \max_{s=1, \ldots, n} \left( \frac{\partial f_{w_1}}{\partial w_{k,i,j}^{(l)}}(X_s) - \frac{\partial f_{w_2}}{\partial w_{k,i,j}^{(l)}}(X_s) \right)^2.
\]

By (60) we know that

\[
\frac{\partial f_w}{\partial w_{k,i,j}^{(l)}}(x)
\]

for fixed \(x \in [-\alpha_n, \alpha_n]^d\) is a sum of at most \(r^{L-2}\) products where each product contains at most \(2L + 1\) factors. Each of these products contains at most \(L\) factors, that are bounded in absolute value by \(B_n\) except the last one, which is bounded in absolute value by \(\gamma_n^\ast\). Considered as a function in \(w\), these products are Lipschitz continuous with a Lipschitz constant bounded by 1.

According to the proof of Lemma 2 we know that \(f_{k,j}^{(l)}(x)\), which is either bounded by \(\|\sigma\|_\infty\) or \(\alpha_n\), is Lipschitz continuous with a Lipschitz constant bounded by \(\max\{\|\sigma\|_\infty, 1\} \cdot (2r + 1)^l \cdot B_n^l \cdot \alpha_n\). The remaining at most \(L\) factors are bounded by \(\max\{\|\sigma\|_\infty, 1\}\) with a Lipschitz constant bounded by \(c_{121} \cdot (2r + 1)^L \cdot B_{n}^L \cdot \alpha_n \cdot \max\{\|\sigma\|_\infty, 1\}\).

The assertion follows from the following result: If \(g_1, \ldots, g_s : \mathbb{R} \to \mathbb{R}\) are Lipschitz continuous functions with Lipschitz constants \(C_{Lip,g_1}, \ldots, C_{Lip,g_s}\), then

\[
\prod_{l=1}^{s} g_l \text{ and } \sum_{l=1}^{s} g_l
\]

are Lipschitz continuous functions with Lipschitz constant bounded by

\[
\sum_{l=1}^{s} C_{Lip,g_l} \cdot \prod_{k \in \{1, \ldots, s\} \backslash \{l\}} \|g_k\|_\infty \leq s \cdot \max_{l} C_{Lip,g_l} \cdot \prod_{k \in \{1, \ldots, s\} \backslash \{l\}} \|g_k\|_\infty
\]

and by

\[
\sum_{l=1}^{s} C_{Lip,g_l} \leq s \cdot \max_{l} C_{Lip,g_l}
\]

49
respectively. 

This together with the fact that $\sigma$ and $\sigma'$ are bounded yields

$$\sum_{k,i,j,l} \max_{s=1,\ldots,n} \left( \frac{\partial f_{w_1}}{\partial u_{k,i,j}^{(l)}}(X_s) - \frac{\partial f_{w_2}}{\partial u_{k,i,j}^{(l)}}(X_s) \right)^2 \leq c_{122} \cdot K_n \cdot B_n^{4L} \cdot \alpha_n^4 \cdot (\gamma_n^*)^2 \cdot \|w_1 - w_2\|^2.$$ 

Summarizing the above results we get the assertion of Lemma 3. \qed
